

Package ‘RSAGA’

April 18, 2013

Type Package

Title SAGA Geoprocessing and Terrain Analysis in R

Version 0.93-2.1

Date 2013-02-08

Author Alexander Brenning

Maintainer Alexander Brenning <brenning@uwaterloo.ca>

Description RSAGA provides access to geocomputing and terrain analysis functions of SAGA from within R by running the command line version of SAGA. RSAGA furthermore provides several R functions for handling ASCII grids, including a flexible framework for applying local functions (including predict methods of fitted models) and focal functions to multiple grids. SAGA GIS is available under GPLv2 / LGPLv2 licence from <http://sourceforge.net/projects/saga-gis/>.

License GPL-2

SystemRequirements SAGA GIS (2.0.4 - 2.0.8)

Depends gstat, shapefiles, plyr

Collate 'gridtools.R' 'RSAGA-core.R' 'RSAGA-modules.R' 'RSAGA-utils.R'

Repository CRAN

Description

RSAGA provides access to geocomputing and terrain analysis functions of SAGA GIS from within R by running the command line version of SAGA. In addition, several R functions for handling and manipulating ASCII grids are provided, including a flexible framework for applying local functions (including predict methods of fitted models) or focal functions to multiple grids.

Details

Package: RSAGA
Type: Package
Version: 0.93-1
Date: 2011-12-28
License: GPL-2

RSAGA provides direct access to SAGA GIS functions including, for example, a comprehensive set of terrain analysis algorithms for calculating local morphometric properties (slope, aspect, curvature), hydrographic characteristics (size, height, and aspect of catchment areas), and other process-related terrain attributes (potential incoming solar radiation, topographic wetness index, and more). In addition, (R)SAGA provides functions for importing and exporting different grid file formats, and tools for preprocessing grids, e.g. closing gaps or filling sinks.

RSAGA adds a framework for creating custom-defined focal functions, e.g. specialized filter and terrain attributes such as the topographic wind shelter index, within R. This framework can be used to apply predict methods of fitted statistical models to stacks of grids representing predictor variables. Furthermore, functions are provided for conveniently picking values at point locations from a grid using kriging or nearest neighbour interpolation.

RSAGA requires the free SAGA GIS (versions 2.0.4 - 2.0.8 are currently supported) and its user-contributed modules to be available on your computer. These can be downloaded under GPL from <http://sourceforge.net/projects/saga-gis/>. Please check [rsaga.env](#) to make sure that RSAGA can find your local installation of SAGA. You may need to 'tell' RSAGA where to find SAGA GIS.

Thanks to Olaf Conrad, Andre Ringeler and all the other SAGA developers and contributors providing this excellent geocomputing tool! Thanks to Rainer Hurling, Johan van de Wauw and others for helping to adapt SAGA to and test on unix platforms.

centervalue	<i>Pick Center Value from Matrix</i>
-------------	--------------------------------------

Description

Pick the value in the center of a square matrix. Auxiliary function to be used by functions called by [focal.function](#).

Usage

```
centervalue(x)
```

Arguments

x a square matrix

Details

See for example the code of [resid.median](#).

Author(s)

Alexander Brenning

See Also

[focal.function](#), [resid.median](#)

Examples

```
( m <- matrix( round(runif(9,1,10)), ncol=3 ) )
centervalue(m)
```

create.variable.name	<i>Convert file name to variable name</i>
----------------------	-------------------------------------------

Description

Convert a file name into a variable name

Usage

```
create.variable.name(filename, prefix = NULL, fsep = .Platform$file.sep)
```

Arguments

filename	character string
prefix	character string: optional prefix to be added
fsep	character used to separate path components

Author(s)

Alexander Brenning

Examples

```
create.variable.name("C:/my-path/my-file-name.Rd",prefix="res")
```

focal.function	<i>Local and Focal Grid Functions</i>
----------------	---------------------------------------

Description

focal.function cuts out square or circular moving windows from a grid (matrix) and applies a user-defined matrix function to calculate e.g. a terrain attribute or filter the grid. The function is suitable for large grid files as it can process them row by row. local.function represents the special case of a moving window of radius 1. Users can define their own functions operating on moving windows, or use simple functions such as median to define filters.

Usage

```
focal.function(in.grid, in.factor.grid, out.grid.prefix, path = NULL,
  in.path = path, out.path = path, fun, varnames, radius = 0,
  is.pixel.radius = TRUE, na.strings = "NA",
  valid.range = c(-Inf, Inf), nodata.values = c(),
  out.nodata.value, search.mode = c("circle", "square"),
  digits = 4, hdr.digits = 10, dec = ".", quiet = TRUE, nlines = Inf,
  mw.to.vector = FALSE, mw.na.rm = FALSE, ...)
local.function(...)
gapply(in.grid, fun, varnames, mw.to.vector=TRUE, mw.na.rm=TRUE, ...)
```

Arguments

in.grid	file name of input ASCII grid, relative to in.path
in.factor.grid	optional file name giving a gridded categorical variables defining zones; zone boundaries are used as breaklines for the moving window (see Details)
out.grid.prefix	character string (optional), defining a file name prefix to be used for the output file names; a dash (-) will separate the prefix and the varnames
path	path in which to look for in.grid and write output grid files; see also in.path and out.path, which overwrite path if they are specified

<code>in.path</code>	path in which to look for <code>in.grid</code> (defaults to <code>path</code>)
<code>out.path</code>	path in which to write output grid files; defaults to <code>path</code>
<code>fun</code>	a function, or name of a function, to be applied on the moving window; see Details
<code>varnames</code>	character vector specifying the names of the variable(s) returned by <code>fun</code> ; if missing, <code>focal.function</code> will try to determine the <code>varnames</code> from <code>fun</code> itself, or from a call to <code>fun</code> if this is a function (see Details)
<code>radius</code>	numeric value specifying the (circular or square) radius of the moving window; see <code>is.pixel.radius</code> and <code>search.mode</code> ; note that all data within distance $\leq \text{radius}$ will be included in the moving window, not $< \text{radius}$.
<code>is.pixel.radius</code>	logical: if <code>TRUE</code> (default), the <code>radius</code> will be interpreted as a (possibly non-integer) number of pixels; if <code>FALSE</code> , it is interpreted as a radius measured in the grid (map) units.
<code>valid.range</code>	numeric vector of length 2, specifying minimum and maximum valid values read from input file; all values $< \text{valid.range}[1]$ or $> \text{valid.range}[2]$ will be converted to NA.
<code>nodata.values</code>	numeric vector: any values from the input grid file that should be converted to NA, in addition to the <code>nodata</code> value specified in the grid header
<code>out.nodata.value</code>	numeric: value used for storing NAs in the output file(s); if missing, use the same <code>nodata</code> value as specified in the header of the input grid file
<code>na.strings</code>	passed on to scan
<code>search.mode</code>	character, either <code>"circle"</code> (default) for a circular search window, or <code>"square"</code> for a squared one.
<code>digits</code>	numeric, specifying the number of digits to be used for output grid file.
<code>hdr.digits</code>	numeric, specifying the number of digits to be used for the header of the output grid file (default: 10; see write.ascii.grid.header).
<code>dec</code>	character, specifying the decimal mark to be used for input and output.
<code>quiet</code>	If <code>TRUE</code> , gives some output (" <code>*</code> ") after every 10th line of the grid file and when the job is done.
<code>nlines</code>	Number of lines to be processed; useful for testing purposes.
<code>mw.to.vector</code>	logical: Should the content of the moving window be coerced (from a matrix) to a vector?
<code>mw.na.rm</code>	logical: Should NAs be removed from moving window prior to passing the data to <code>fun</code> ? Only applicable when <code>mw.to.vector=TRUE</code> .
<code>...</code>	Arguments to be passed to <code>fun</code> ; <code>local.function</code> : arguments to be passed to <code>focal.function</code> .

Details

`focal.function` passes a square matrix of size $2 \times \text{radius} + 1$ to the function `fun` if `mw.to.vector=FALSE` (default), or a vector of length $\leq (2 \times \text{radius} + 1)^2$ if `mw.to.vector=TRUE`. This matrix or vector

will contain the content of the moving window, which may possibly contain NAs even if the `in.grid` has no nodata values, e.g. due to edge effects. If `search.mode="circle"`, values more than `radius` units (pixels or grid units, depending on `is.pixel.radius`) away from the center pixel / matrix entry will be set to NA. In addition, `valid.range`, `nodata.values`, and the nodata values specified in the `in.grid` are checked to assign further NAs to pixels in the moving window. Finally, if `in.factor.grid` specifies zones, all pixels in the moving window that belong to a different zone than the center pixel are set to NA, or, in other words, zone boundaries are used as breaklines.

The function `fun` should return a single numeric value or a numeric vector. As an example, the function `resid.minmedmax` returns the minimum, median and maximum of the difference between the values in the moving window and the value in the center grid cell. In addition to the (first) argument receiving the moving window data, `fun` may have additional arguments; the `...` argument of `focal.function` is passed on to `fun`. `resid.quantile` is a function that uses this feature.

Optionally, `fun` should support the following feature: If no argument is passed to it, then it should return a character vector giving variable names to be used for naming the output grids. The call `resid.minmedmax()`, for example, returns `c("rmin", "rmed", "rmax")`; this vector must have the same length as the numeric vector returned when moving window data is passed to the function. This feature is only used if no `varnames` argument is provided. Note that the result is currently being abbreviated to a length of 6 characters.

Input and output file names are built according to the following schemes:

Input: `[<in.path>/]<in.grid> Zones: [<in.path>/]<in.factor.grid>` (if specified) Output: `[<out.path>/][<out.grid.prefix>-]<varnames>.asc`

For the input files, `.asc` is used as the default file extension, if it is not specified by the user.

Value

`focal.function` and `local.function` return the character vector of output file names.

Note

These functions are not very efficient ways of calculating e.g. (focal) terrain attributes compared to for example the SAGA modules, but the idea is that you can easily specify your own functions without starting to mess around with C code. For example try implementing a median filter as a SAGA module... or just use the code shown in the example!

Examples

```
## Not run:
# A simple median filter applied to dem.asc:
gapply("dem", "median", radius=3)
# Same:
#focal.function("dem", fun="median", radius=3, mw.to.vector=TRUE, mw.na.rm=TRUE)
# See how the filter has changed the elevation data:
d1 = as.vector(read.ascii.grid("dem")$data)
d2 = as.vector(read.ascii.grid("median")$data)
hist(d1-d2, br=50)

## End(Not run)
# Wind shelter index used by Plattner et al. (2004):
## Not run:
ctrl = wind.shelter.prep(6, -pi/4, pi/12, 10)
focal.function("dem", fun=wind.shelter, control=ctrl,
               radius=6, search.mode="circle")

## End(Not run)
# Or how about this, if "aspect" is local terrain exposure:
## Not run:
gapply("aspect", "cos") # how "northerly-exposed" is a pixel?
gapply("aspect", "sin") # how "easterly-exposed" is a pixel?
# Same result, but faster:
focal.function("aspect", fun=function(x) c(cos(x), sin(x)), varnames=c("cos", "sin"))

## End(Not run)
```

grid.predict

Helper function for applying predict methods to stacks of grids.

Description

This function can be used to apply the predict method of hopefully any fitted predictive model pixel by pixel to a stack of grids representing the explanatory variables. It is intended to be called primarily by [multi.local.function](#) or [multi.focal.function](#).

Usage

```
grid.predict(fit, predfun, trafo, control.predict,
             predict.column, trace = 0, location, ...)
```

Arguments

<code>fit</code>	a model object for which prediction is desired
<code>predfun</code>	optional prediction function; if missing, the fit's <code>predict</code> method is called. In some cases it may be convenient to define a wrapper function for the predict method that may be passed as <code>predfun</code> argument.
<code>trafo</code>	an optional function(x) that takes a data.frame x and returns a data.frame with the same number of rows; this is intended to perform transformations on the input variables, e.g. derive a log-transformed variable from the raw input read from the grids, or more complex variables such as the NDVI etc.; the data.frame resulting from a call to <code>trafo</code> (if provided) is passed to <code>predfun</code>
<code>control.predict</code>	an optional list of arguments to be passed on to <code>predfun</code> ; this may be e.g. <code>type="response"</code> to obtain probability prediction maps from a logistic regression model
<code>predict.column</code>	optional character string: Some predict methods (e.g. <code>predict.lda</code>) return a data.frame with several columns, e.g. one column per class in a classification problem. <code>predict.column</code> is used to pick the one that is of interest
<code>trace</code>	integer ≥ 0 : positive values give more ($=2$) or less ($=1$) information on predictor variables and predictions
<code>location</code>	optional location data received from <code>multi.focal.function</code> ; is added to the <code>newdata</code> object that is passed on to <code>predfun</code> .
<code>...</code>	these arguments are provided by the calling function, usually <code>multi.local.function</code> or <code>multi.focal.function</code> . They contain the explanatory (predictor) variables required by the fit model.

Details

`grid.predict` is a simple wrapper function. First it binds the arguments in `...` together in a data.frame with the raw predictor variables that have been read from their grids by the caller, `multi.local.function` (or `multi.focal.function`). Then it calls the optional `trafo` function to transform or combine predictor variables (e.g. perform log transformations, ratioing, arithmetic operations such as calculating the NDVI). Finally the `predfun` (or, typically, the default `predict` method of `fit`) is called, handing over the `fit`, the predictor data.frame, and the optional `control.predict` arguments.

Value

`grid.predict` returns the result of the call to `predfun` or the default `predict` method.

Note

Though `grid.predict` can in principle deal with predict methods returning factor variables, its usual caller `multi.local.function` / `multi.focal.function` cannot; classification models should be dealt with by setting a `type="prob"` (for `rpart`) or `type="response"` (for logistic regression and logistic additive model) argument, for example (see second Example below).

Examples

```
## Not run:
# Assume that d is a data.frame with point observations
# of a numerical response variable y and predictor variables
# a, b, and c.
# Fit a generalized additive model to y,a,b,c.
# We want to model b and c as nonlinear terms:
require(gam)
fit <- gam(y ~ a + s(b) + s(c), data = d)
multi.local.function(in.grids = c("a", "b", "c"),
  out.varnames = "pred",
  fun = grid.predict, fit = fit )
# Note that the 'grid.predict' uses by default the
# predict method of 'fit'.
# Model predictions are written to a file named pred.asc

## End(Not run)

## Not run:
# A fake example of a logistic additive model:
require(gam)
fit <- gam(cl ~ a + s(b) + s(c), data = d, family = binomial)
multi.local.function(in.grids = c("a", "b", "c"),
  out.varnames = "pred",
  fun = grid.predict, fit = fit,
  control.predict = list(type = "response") )
# 'control.predict' is passed on to 'grid.predict', which
# dumps its contents into the arguments for 'fit''s
# 'predict' method.
# Model predictions are written to a file named pred.asc

## End(Not run)
```

`grid.to.xyz`*Convert Grid Matrix to (x,y,z) data.frame*

Description

Convert a grid matrix to a (x,y,z) data.frame.

Usage

```
grid.to.xyz(data, header, varname = "z", colnames = c("x", "y", varname))
```

Arguments

<code>data</code>	grid data: either a grid data matrix, or a list with components <code>data</code> (a matrix with the grid data) and <code>header</code> (the grid header information); see read.ascii.grid for details
<code>header</code>	optional list giving grid header information; see read.ascii.grid for details
<code>varname</code>	character: name to
<code>colnames</code>	names to be given to the columns corresponding to the x and y coordinates and the grid variable in the output data.frame

Value

a data.frame with three columns (names are specified in the `colnames` argument) giving the x and y coordinates and the attribute values at the locations given by the grid data

str(xyz)

## End(Not run)
```

match.arg.ext

*Extended Argument Matching***Description**

match.arg.ext matches arg against a set of candidate values as specified by choices; it extends [match.arg](#) by allowing arg to be a numeric identifier of the choices.

Usage

```
match.arg.ext(arg, choices, base = 1, several.ok = FALSE,
              numeric = FALSE, ignore.case = FALSE)
```

Arguments

arg	a character string or numeric value
choices	a character vector of candidate values
base	numeric value, specifying the numeric index assigned to the first element of choices
several.ok	logical specifying if arg should be allowed to have more than one element
numeric	logical specifying if the function should return the numerical index (counting from base) of the matched argument, or, by default, its name
ignore.case	logical specifying if the matching should be case sensitive

Details

When choices are missing, they are obtained from a default setting for the formal argument arg of the function from which match.arg.ext was called.

Matching is done using [pmatch](#) (indirectly through a call to [match.arg](#), so arg may be abbreviated.

If arg is numeric, it may take values between base and length(choices)+base-1. base=1 will give standard 1-based R indices, base=0 will give indices counted from zero as used to identify SAGA modules in library RSAGA.

Value

If numeric is false and arg is a character string, the function returns the unabbreviated version of the unique partial match of arg if there is one; otherwise, an error is signalled if several.ok is false, as per default. When several.ok is true and there is more than one match, all unabbreviated versions of matches are returned.

If numeric is false but arg is numeric, match.arg.ext returns name of the match corresponding to this index, counting from base; i.e. arg=base corresponds to choices[1].

If numeric is true, the function returns the numeric index(es) of the partial match of arg, counted from base to length(choices)+base-1. If arg is already numeric, the function only checks whether it falls into the valid range from arg to length(choices)+base-1 and returns arg.

Author(s)

Alexander Brenning

See Also[match.arg](#), [pmatch](#)**Examples**

```
# Based on example from 'match.arg':
require(stats)
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg.ext(type, base=0)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
center(x, "t")      # Works
center(x, 2)        # Same, for base=0
center(x, "med")    # Works
center(x, 1)        # Same, for base=0
try(center(x, "m")) # Error
```

multi.focal.function *Local and Focal Grid Function with Multiple Grids as Inputs*

Description

`multi.focal.function` cuts out square or circular moving windows from a stack of grids (matrices) and applies a user-defined matrix function that takes multiple arguments to this data. `multi.local.function` is a more efficiently coded special case of moving windows of size 0, i.e. functions applied to individual grid cells of a stack of grids. This is especially useful for applying predict methods of statistical models to a stack of grids containing the explanatory variables (see Examples and [grid.predict](#)). The function is suitable for large grid files as it can process them row by row; but it may be slow because one call to the focal function is generated for each grid cell.

Usage

```
multi.local.function(in.grids, in.grid.prefix, out.grid.prefix,
  path = NULL, in.path = path, out.path = path,
  fun, in.varnames, out.varnames, na.strings = "NA",
  valid.ranges, nodata.values = c(), out.nodata.value,
  digits = 4, hdr.digits = 10, dec = ".", quiet = TRUE, nlines = Inf,
  na.action = na.exclude, pass.location = FALSE,
  ... )
multi.focal.function(in.grids, in.grid.prefix, in.factor.grid,
```

```

out.grid.prefix, path = NULL, in.path = path, out.path = path,
fun, in.varnames, out.varnames, radius = 0, is.pixel.radius = TRUE,
na.strings = "NA",
valid.ranges, nodata.values = c(), out.nodata.value,
search.mode = c("circle","square"), digits = 4,
hdr.digits = 10, dec = ".", quiet = TRUE, nlines = Inf,
mw.to.vector = FALSE, mw.na.rm = FALSE, pass.location = FALSE, ... )

```

Arguments

<code>in.grids</code>	character vector: file names of input ASCII grids, relative to <code>in.path</code> ; <code>in.grid.prefix</code> will be used as a prefix to the file name if specified; default file extension: <code>.asc</code>
<code>in.factor.grid</code>	optional file name giving a gridded categorical variables defining zones; zone boundaries are used as breaklines for the moving window (see Details)
<code>in.grid.prefix</code>	character string (optional), defining a file name prefix to be used for the input file names; a dash (-) will separate the prefix and the <code>in.varnames</code>
<code>out.grid.prefix</code>	character string (optional), defining a file name prefix to be used for the output file names; a dash (-) will separate the prefix and the <code>out.varnames</code>
<code>path</code>	path in which to look for <code>in.grids</code> and write output grid files; see also <code>in.path</code> and <code>out.path</code> , which overwrite <code>path</code> if they are specified
<code>in.path</code>	path in which to look for <code>in.grids</code> (defaults to <code>path</code>)
<code>out.path</code>	path in which to write output grid files; defaults to <code>path</code>
<code>fun</code>	a function, or name of a function, to be applied on the moving window; see Details; <code>fun</code> is expected to accept named arguments with the names given by <code>in.varnames</code> ; <code>grid.predict</code> is a wrapper function that can be used for applying a model's <code>predict</code> method to a stack of grids; see Details. In <code>multi.local.function</code> , <code>fun</code> must be able to process arguments that are vectors of equal length (e.g., a vector of 50 slope angles, another vector of 50 elevation values, etc.).
<code>in.varnames</code>	character vector: names of the variables corresponding to the <code>in.grids</code> ; if missing, same as <code>in.grids</code> ; if specified, must have the same length and order as <code>in.grids</code>
<code>out.varnames</code>	character vector specifying the name(s) of the variable(s) returned by <code>fun</code> ; if missing, <code>multi.focal.function</code> will try to determine the <code>varnames</code> from <code>fun</code> itself, or from a call to <code>fun</code> if this is a function (see Details)
<code>radius</code>	numeric value specifying the (circular or square) radius of the moving window; see <code>is.pixel.radius</code> and <code>search.mode</code> ; note that all data within distance $\leq \text{radius}$ will be included in the moving window, not $< \text{radius}$.
<code>is.pixel.radius</code>	logical: if <code>TRUE</code> (default), the <code>radius</code> will be interpreted as a (possibly non-integer) number of pixels; if <code>FALSE</code> , it is interpreted as a radius measured in the grid (map) units.
<code>valid.ranges</code>	optional list of length <code>length(in.grids)</code> with numeric vector of length 2, specifying minimum and maximum valid values read from input file; all values $< \text{valid.ranges}[[i]][1]$ or $> \text{valid.ranges}[[i]][2]$ will be converted to <code>NA</code> .

<code>nodata.values</code>	numeric vector: any values from the input grid file that should be converted to NA, in addition to the nodata value specified in the grid header
<code>out.nodata.value</code>	numeric: value used for storing NAs in the output file(s); if missing, use the same nodata value as specified in the header of the input grid file
<code>search.mode</code>	character, either "circle" (default) for a circular search window, or "square" for a squared one.
<code>digits</code>	numeric, specifying the number of digits to be used for output grid file.
<code>hdr.digits</code>	numeric, specifying the number of digits to be used for the header of the output grid file (default: 10; see write.ascii.grid.header).
<code>dec</code>	character, specifying the decimal mark to be used for input and output.
<code>quiet</code>	If FALSE, gives some output ("*") after every 10th line of the grid file and when the job is done.
<code>nlines</code>	Number of lines to be processed; useful for testing purposes.
<code>na.action</code>	function: determines if/how NA values are omitted from the stack of input variables; use na.exclude (default) or na.pass if fun can handle NA values correctly
<code>mw.to.vector</code>	logical: Should the content of the moving window be coerced (from a matrix) to a vector?
<code>mw.na.rm</code>	logical: Should NAs be removed from moving window prior to passing the data to fun? Only applicable when <code>mw.to.vector=TRUE</code> .
<code>pass.location</code>	logical: Should the x,y coordinates of grid points (center of grid cells) be passed to fun? If TRUE, two additional arguments named arguments x and y are passed to fun; NOTE: This currently only works for radius=0, otherwise a warning is produced and <code>pass.location</code> is reset to FALSE.
<code>na.strings</code>	passed on to scan
<code>...</code>	Arguments to be passed to fun; <code>local.function</code> : arguments to be passed to <code>focal.function</code> .

Details

`multi.local.function` is probably most useful for applying the predict method of a fitted model to a grids representing the predictor variables. An example is given below and in more detail in Brenning (2008) (who used `multi.focal.function` for the same purpose); see also [grid.predict](#).

`multi.local.function` is essentially the same as `multi.focal.function` for `radius=0`, but coded MUCH more efficiently. (The relevant code will eventually migrate into `multi.focal.function` as well, but requires further testing.) Applying a GAM to the data set of Brenning (2008) takes about 1/100th the time with `multi.local.function` compared to `multi.focal.function`.

`multi.focal.function` extends [focal.function](#) by allowing multiple input grids to be passed to the focal function fun operating on moving windows. It passes square matrices of size $2 \times \text{radius} + 1$ to the function fun if `mw.to.vector=FALSE` (default), or a vector of length $\leq (2 \times \text{radius} + 1)^2$ if `mw.to.vector=TRUE`; one such matrix or vector per input grid will be passed to fun as an argument whose name is specified by `in.varnames`.

These matrices or vectors will contain the content of the moving window, which may possibly contain NAs even if the `in.grid` has no nodata values, e.g. due to edge effects. If `search.mode="circle"`, values more than `radius` units (pixels or grid units, depending on `is.pixel.radius`) away from the center pixel / matrix entry will be set to NA. In addition, `valid.range`, `nodata.values`, and the nodata values specified in the `in.grid` are checked to assign further NAs to pixels in the moving window. Finally, if `in.factor.grid` specifies zones, all pixels in the moving window that belong to a different zone than the center pixel are set to NA, or, in other words, zone boundaries are used as breaklines.

The function `fun` should return a single numeric value or a numeric vector, such as a regression result or a vector of class probabilities returned by a soft classifier. In addition to the named arguments receiving the moving window data, `fun` may have additional arguments; the `...` argument of `focal.function` is passed on to `fun`. `grid.predict` uses this feature.

Optionally, `fun` should support the following feature: If no argument is passed to it, then it should return a character vector giving variable names to be used for naming the output grids.

For the input files, `.asc` is used as the default file extension, if it is not specified by the user.

See `focal.function` for details.

Value

`multi.focal.function` returns the character vector of output file names.

Note

`multi.focal.function` can do all the things `focal.function` can do.

Examples

```
## Not run:
# Assume that d is a data.frame with point observations
# of a numerical response variable y and predictor variables
# a, b, and c.
# Fit a generalized additive model to y,a,b,c.
# We want to model b and c as nonlinear terms:
```

```

require(gam)
fit <- gam(y ~ a + s(b) + s(c), data = d)
multi.local.function(in.grids = c("a", "b", "c"),
  out.varnames = "pred",
  fun = grid.predict, fit = fit )
  # Note that the 'grid.predict' uses by default the
  # predict method of 'fit'.
# Model predictions are written to a file named pred.asc

## End(Not run)

## Not run:
# A fake example of a logistic additive model:
require(gam)
fit <- gam(cl ~ a + s(b) + s(c), data = d, family = binomial)
multi.local.function(in.grids = c("a", "b", "c"),
  out.varnames = "pred",
  fun = grid.predict, fit = fit,
  control.predict = list(type = "response") )
  # 'control.predict' is passed on to 'grid.predict', which
  # dumps its contents into the arguments for 'fit's
  # 'predict' method.
# Model predictions are written to a file named pred.asc

## End(Not run)

```

pick.from.points

Pick Variable from Spatial Dataset

Description

These functions pick (i.e. interpolate without worrying too much about theory) values of a spatial variables from a data stored in a data.frame, a point shapefile, or an ASCII or SAGA grid, using nearest neighbor or kriging interpolation. `pick.from.points` and `[internal.]pick.from.ascii.grid` are the core functions that are called by the different wrappers.

Usage

```

pick.from.points(data, src, pick,
  method = c("nearest.neighbour", "krige"),
  set.na = FALSE, radius = 200, nmin = 0, nmax = 100,
  sill = 1, range = radius, nugget = 0,
  model = vgm(sill - nugget, "Sph", range = range, nugget = nugget),
  log = rep(FALSE, length(pick)), X.name = "x", Y.name = "y", cbind = TRUE)
pick.from.shapefile(data, shapefile, X.name = "x", Y.name = "y", ...)
pick.from.ascii.grid(data, file, path = NULL, varname = NULL, prefix = NULL,
  method = c("nearest.neighbour", "krige"), cbind = TRUE,
  parallel = FALSE, nsplit, quiet = TRUE, ...)
pick.from.saga.grid(data, filename, path, varname, prec = 7,

```

```

show.output.on.console = FALSE, env = rsaga.env(), ...)
pick.from.ascii.grids(data, file, path = NULL, varname = NULL, prefix = NULL,
  cbind = TRUE, quiet = TRUE, ...)
internal.pick.from.ascii.grid(data, file, path = NULL, varname = NULL, prefix = NULL,
  method = c("nearest.neighbour", "krige"), nodata.values = c(-9999, -99999),
  at.once, quiet = TRUE, X.name = "x", Y.name = "y",
  nlines = Inf, cbind = TRUE, range, radius, na.strings = "NA", ...)

```

Arguments

<code>data</code>	data.frame giving the coordinates (in columns specified by <code>X.name</code> , <code>Y.name</code>) of point locations at which to interpolate the specified variables or grid values
<code>src</code> , <code>shapefile</code>	data.frame or point shapefile
<code>pick</code>	variables to be picked (interpolated) from <code>src</code> ; if missing, use all available variables, except those specified by <code>X.name</code> and <code>Y.name</code>
<code>method</code>	interpolation method to be used; uses a partial match to the alternatives <code>"nearest.neighbor"</code> (currently the default) and <code>"krige"</code>
<code>set.na</code>	logical: if a column with a name specified in <code>pick</code> already exists in <code>data</code> , how should it be dealt with? <code>set.na=FALSE</code> (default) only overwrites existing data if the interpolator yields a non-NA result; <code>set.na=TRUE</code> passes NA values returned by the interpolator on to the results data.frame
<code>radius</code>	numeric value specifying the radius of the local neighborhood to be used for interpolation; defaults to 200 map units (presumably meters), or, in the functions for grid files, <code>2.5*cellsize</code> .
<code>nmin</code> , <code>nmax</code>	numeric, for <code>method="krige"</code> only: see <code>krige</code> function in package gstat
<code>sill</code>	numeric, for <code>method="krige"</code> only: the overall sill parameter to be used for the variogram
<code>range</code>	numeric, for <code>method="krige"</code> only: the variogram range
<code>nugget</code>	numeric, for <code>method="krige"</code> only: the nugget effect
<code>model</code>	for <code>method="krige"</code> only: the variogram model to be used for interpolation; defaults to a spherical variogram with parameters specified by the <code>range</code> , <code>sill</code> , and <code>nugget</code> arguments; see <code>vgm</code> in package gstat for details
<code>log</code>	logical vector, specifying for each variable in <code>pick</code> if interpolation should take place on the logarithmic scale (default: <code>FALSE</code>)
<code>X.name</code> , <code>Y.name</code>	names of the variables containing the x and y coordinates
<code>cbind</code>	logical: should the new variables be added to the input data.frame (<code>cbind=TRUE</code> , the default), or should they be returned as a separate vector or data.frame? <code>cbind=FALSE</code>
<code>file</code>	file name (relative to <code>path</code> , default file extension <code>.asc</code>) of an ASCII grid from which to pick a variable, or an open connection to such a file
<code>path</code>	optional path to file
<code>varname</code>	character string: a variable name for the variable interpolated from grid file in <code>pick.from.*.grid</code> ; if missing, variable name will be determined from filename by a call to <code>create.variable.name</code>

prefix	an optional prefix to be added to the varname
nodata.values	numeric vector specifying grid values that should be converted to NA; in addition to the values specified here, the nodata value given in the input grid's header will be used
at.once	logical: should the grid be read as a whole or line by line? at.once=FALSE is useful for processing large grids that do not fit into memory; the argument is currently by default FALSE for method="nearest.neighbour", and it currently MUST be TRUE for all other methods (in these cases, TRUE is the default value); piecewise processing with at.once=FALSE is always faster than processing the whole grid at.once
quiet	logical: provide information on the progress of grid processing on screen? (only relevant if at.once=FALSE and method="nearest.neighbour")
nlines	numeric: stop after processing nlines lines of the input grid; useful for testing purposes
filename	character: name of a SAGA grid file, default extension .sgrd
prec	numeric, specifying the number of digits to be used in converting a SAGA grid to an ASCII grid in pick.from.saga.grid
na.strings	passed on to scan
env	list: RSAGA geoprocessing environment created by rsaga.env
show.output.on.console	a logical (default: FALSE), indicates whether to capture the output of the command and show it on the R console (see system , rsaga.geoprocessor).
nsplit	split the data.frame data in nsplit disjoint subsets in order to increase efficiency by using ddpoly in package plyr . The default seems to perform well in many situations.
parallel	logical (default: FALSE): enable parallel processing; requires additional packages such as doSMP or doMC . See example below and ddply
...	arguments to be passed to pick.from.points, and to internal.pick.from.ascii.grid in the case of pick.from.ascii.grid

Details

pick.from.points interpolates the variables defined by pick in the src data.frame to the locations provided by the data data.frame. Only nearest neighbour and ordinary kriging interpolation are currently available. This function is intended for 'data-rich' situations in which not much thought needs to be put into a geostatistical analysis of the spatial structure of a variable. In particular, this function is supposed to provide a simple, 'quick-and-dirty' interface for situations where the src data points are very densely distributed compared to the data locations.

pick.from.shapefile is a front-end of pick.from.points for point shapefiles.

pick.from.ascii.grid retrieves data values from an ASCII raster file using either nearest neighbour or ordinary kriging interpolation. The latter may not be possible for large raster data sets because the entire grid needs to be read into an R matrix. Split-apply-combine strategies are used to improve efficiency and allow for parallelization.

The optional parallelization of pick.from.ascii.grid computation requires the use of a *parallel backend* package such as **doSMP** or **doMC**, and the parallel backend needs to be registered before

calling this function with `parallel=TRUE`. The example section provides an example using **doSMP** on Windows. I have seen 25-40 in some examples that I ran on a dual core Windows computer.

`pick.from.ascii.grids` performs multiple `pick.from.ascii.grid` calls. File path and prefix arguments may be specific to each file (i.e. each may be a character vector), but all interpolation settings will be the same for each file, limiting the flexibility a bit compared to individual `pick.from.ascii.grid` calls by the user. `pick.from.ascii.grids` currently processes the files sequentially (i.e. parallelization is limited to the `pick.from.ascii.grid` calls within this function).

`pick.from.saga.grid` is the equivalent to `pick.from.ascii.grid` for SAGA grid files. It simply converts the SAGA grid file to a (temporary) ASCII raster file and applies `pick.from.ascii.grid`.

`internal.pick.from.ascii.grid` is an internal 'workhorse' function that by itself would be very inefficient for large data sets data. This function is called by `pick.from.ascii.grid`, which uses a split-apply-combine strategy implemented in the **plyr** package.

Value

If `cbind=TRUE`, columns with the new, interpolated variables are added to the input `data.frame` data.

If `cbind=FALSE`, a `data.frame` only containing the new variables is returned (possibly coerced to a vector if only one variable is processed).

Note

`method="krige"` requires the **gstat** package.

`pick.from.shapefile` requires the **shapefiles** package.

The nearest neighbour interpolation currently randomly breaks ties if `pick.from.points` is used, and in a deterministic fashion (rounding towards greater grid indices, i.e. toward south and east) in the grid functions.

Examples

```
## Not run:
# assume that 'dem' is an ASCII grid and d a data.frame with variables x and y
pick.from.ascii.grid(d, "dem")
# parallel processing on Windows using the doSMP package:
require(doSMP)
workers = startWorkers(workerCount = 2) # DualCore processor
registerDoSMP(workers)
pick.from.ascii.grid(d, "dem")
# produces two warning messages when using doSMP
# typically 25-40
stopWorkers(workers)

## End(Not run)

# use the meuse data for some tests:
require(gstat)
data(meuse)
data(meuse.grid)
meuse.nn = pick.from.points(data=meuse.grid, src=meuse,
  pick=c("cadmium", "copper", "elev"), method="nearest.neighbour")
meuse.kr = pick.from.points(data=meuse.grid, src=meuse,
  pick=c("cadmium", "copper", "elev"), method="krige", radius=100)
# it does make a difference:
plot(meuse.kr$cadmium, meuse.nn$cadmium)
plot(meuse.kr$copper, meuse.nn$copper)
plot(meuse.kr$elev, meuse.nn$elev)
```

read.ascii.grid

Read/write ASCII, SAGA and Rd Grid Files

Description

These functions provide simple interfaces for reading and writing grids from/to ASCII grids and Rd files. Grids are stored as matrices, their headers in lists.

Usage

```
read.ascii.grid(file, return.header = TRUE, print = 0,
  nodata.values = c(), at.once = TRUE, na.strings = "NA")
read.ascii.grid.header(file, ...)
read.sgrd(fname, return.header = TRUE, print = 0,
  nodata.values = c(), at.once = TRUE, prec = 7, ...)
read.Rd.grid(fname, return.header = TRUE)

write.ascii.grid(data, file, header = NULL, write.header = TRUE,
  digits, hdr.digits = 10, dec = ".", georef = "corner")
write.ascii.grid.header(file, header, georef, dec = ".", hdr.digits = 10)
write.sgrd(data, file, header = NULL, prec = 7, hdr.prec = 10,
```

```

    georef = "corner", ...)
write.Rd.grid(data, file, header = NULL, write.header = TRUE,
              compress = TRUE)

```

Arguments

file	file name of an ASCII grid (extension defaults to .asc if not specified), or a connection open for reading or writing, as required
fname	file name of a grid stored as an R (.Rd) file; extension defaults to .Rd
return.header	logical: should the grid header be returned (default), or just the grid data matrix? In the former case, read.ascii.grid returns a list with two components named data and header.
print	numeric, specifying how detailed the output reporting the progress should be (currently 0 to 2, 0 being minimum output).
nodata.values	optional numeric vector specifying nodata values to be used in addition to the nodata value specified in the grid header; nodata values are converted to NA.
at.once	logical: if TRUE, read the whole grid with one scan command; if FALSE, read it row by row using scan with option nlines=1.
data	grid data: a data matrix, or a list with components data (the grid data matrix) and header (the grid header information).
header	optional list argument specifying the grid header information as returned by the read.ascii.grid or read.ascii.grid.header function; see Details
write.header	logical: should the header be written with the grid data? (default: TRUE)
digits	numeric: if not missing, write data rounded to this many decimal places
hdr.digits, hdr.prec	numeric: write (non-integer) header data with this many decimal places; a value of 9 or higher is recommended for compatibility with SAGA GIS (default: 10)
dec	character (default: "."): decimal mark used in input or output file
georef	character: specifies whether the output grid should be georeferenced by the "center" or "corner" of its lower left grid cell; defaults to "corner".
compress	logical: should the .Rd file written by write.Rd.file be compressed? (default: TRUE)
prec	integer: number of digits of temporary ASCII grid used for importing or exporting a SAGA grid
na.strings	passed on to scan .
...	read.sgrd, write.sgrd: additional arguments to be passed to rsaga.geoprocessor

Value

The read.* functions return either a list with components data (the grid data matrix) and header (the grid header information, see below), if return.header=TRUE, or otherwise just the grid data matrix return.header=FALSE.

The grid data matrix is a numeric matrix whose first column corresponds to the first (i.e. northern-most) row of the grid. Columns run from left = West to right = East.

The header information returned by the `read.ascii.grid[.header]` functions (if `return.header=TRUE`) is a list with the following components:

<code>ncols</code>	Number of grid columns.
<code>nrows</code>	Number of grid rows.
<code>xllcorner</code>	x coordinate of the corner of the lower left grid cell.
<code>yllcorner</code>	y coordinate of the corner of the lower left grid cell.
<code>cellsize</code>	Single numeric value specifying the size of a grid cell or pixel in both x and y direction.
<code>nodata_value</code>	Single numeric value being interpreted as NA (typically -9999).
<code>xllcenter</code>	x coordinate of the center of the lower left grid cell
<code>yllcenter</code>	y coordinate of the center of the lower left grid cell

Note: The order of the components, especially of `?llcorner` and `?llcenter`, may change, depending on the order in which they appear in the grid header and on the georeferencing method (center or corner) used for the grid. The `?llcorner` and `?llcenter` attributes differ only by `cellsize/2`.

Note

`read.sgrd` and `write.sgrd` import/export grids indirectly by creating temporary ASCII grid files (this explains why `write.sgrd` has `prec` and `hdr.prec` arguments). Consider using `readGDAL` and `writeGDAL` in package `rgdal` instead, which are likely more efficient but may require coercion of your gridded data to/from a `Spatial...DataFrame`-class.

The `read.Rd.grid` and `write.Rd.grid` functions use the `load` and `save` commands to store a grid. The variable name used is `data`, which is either a numeric matrix or a list with components `data` (the grid data matrix) and `header` (the grid header information).

`readGDAL` and `writeGDAL` in package `rgdal`, and `readAsciiGrid` and `writeAsciiGrid` in package `maptools`

<code>relative.position</code>	<i>Relative Topographic Position</i>
--------------------------------	--------------------------------------

Description

`relative.position` and `relative.rank` are used with [focal.function](#) to determine the relative value of a grid cell compared to its surroundings, either on a metric scale or based on ranks.

Usage

```
relative.position(x)
relative.rank(x, ties.method="average")
```

Arguments

x	a square matrix with the grid data from the moving window, possibly containing NA values
ties.method	see rank

Value

If x is provided, a numeric value in the interval [0,1] is returned.

If x is missing, a character vector of same length giving suggested variable (or file) names, here "relpos" and "relrank", respectively. See [focal.function](#) for details.

Author(s)

Alexander Brenning

[focal.function](#), [rank](#), [centervalue](#)

Examples

```
m = matrix( round(runif(9,1,10)), ncol=3 )
print(m)
relative.position(m)
relative.rank(m)
## Not run:
focal.function("dem",fun=relative.rank,radius=5)
focal.function("dem",fun=relative.position,radius=5)
relrank = as.vector(read.ascii.grid("relrank")$data)
relpos = as.vector(read.ascii.grid("relpos")$data)
plot(relpos,relrank,pch=".")
cor(relpos,relrank,use="complete.obs",method="pearson")

## End(Not run)
```

resid.median

Residual Median and Quantile Filters for Grids

Description

These functions use the median and other quantiles to describe the difference between a grid value and its neighborhood. They are designed for use with [focal.function](#).

Usage

```

resid.median(x)
resid.minmedmax(x)
resid.quantiles(x)
resid.quantile(x, probs)

```

Arguments

<code>x</code>	a square matrix with the grid data from the moving window, possibly containing NA values
<code>probs</code>	numeric vector of probabilities in [0,1] to be passed to quantile

Details

These functions are designed for being called by [focal.function](#), which repeatedly passes the contents of a square or circular moving window to these functions.

The `resid.median` function rests the value of the central grid cell from the median of the whole moving window. Thus, in terms of topography, a positive residual median indicates that this grid cell stands out compared to its surroundings. `resid.quantile` gives more flexibility in designing such residual attributes.

Value

If `x` is provided, a numeric vector of length 1 (`resid.median`), 3 (`resid.minmedmax` and `resid.quantiles`), or `length(probs)` (`resid.quantile`).

If `x` is missing, a character vector of same length giving suggested variable (or file) names, such as "rmed". See [focal.function](#) for details.

Author(s)

Alexander Brenning

```
rsaga.add.grid.values.to.points
```

Add Grid Values to Point Shapefile

Description

Pick values from SAGA grids and attach them as a new variables to a point shapefile.

Usage

```
rsaga.add.grid.values.to.points(in.shapefile, in.grids, out.shapefile,
  method = c("nearest.neighbour", "bilinear",
    "idw", "bicubic.spline", "b.spline"), ...)
```

Arguments

<code>in.grids</code>	Input: character vector with names of (one or more) SAGA grid files to be converted into a point shapefile.
<code>in.shapefile, out.shapefile</code>	In/Output: point shapefiles (default extension: .shp).
<code>method</code>	interpolation method to be used; choices: nearest neighbour interpolation (default), bilinear interpolation, inverse distance weighting, bicubic spline interpolation, B-splines.
<code>...</code>	Optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment.

Details

Retrieves information from the selected grids at the positions of the points of the selected points layer and adds it to the resulting layer.

Note

This function uses module `Add Grid Values to Points` (code: 0) in SAGA library `shapes_grid`.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA modules)

See Also

[pick.from.points](#), [pick.from.ascii.grid](#), [pick.from.saga.grid](#), [rsaga.grid.to.points](#)

rsaga.close.gaps

SAGA Modules Close Gaps and Close One Cell Gaps

Description

Close (Interpolate) Gaps

Usage

```
rsaga.close.gaps(in.dem, out.dem, threshold = 0.1, ...)
rsaga.close.one.cell.gaps(in.dem, out.dem, ...)
```

Arguments

<code>in.dem</code>	input: digital elevation model (DEM) as SAGA grid file (default file extension: <code>.sgrd</code>)
<code>out.dem</code>	output: DEM grid file without no-data values (gaps). Existing files will be overwritten!
<code>threshold</code>	tension threshold for adjusting the interpolator (default: 0.1)
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Details

`rsaga.close.one.cell.gaps` only fill gaps whose neighbor grid cells have non-missing data.

In `rsaga.close.gaps`, larger tension thresholds can be used to reduce overshoots and undershoots in the surfaces used to fill (interpolate) the gaps.

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses modules 7 (`rsaga.close.gaps`) and 6 (`rsaga.close.one.cell.gaps`) from the SAGA library `grid_tools`.

SAGA GIS 2.0.5+ has a new additional module `Close Gaps with Spline`, which can be accessed using [rsaga.geoprocessor](#) (currently no R wrapper available). See `rsaga.get.usage("grid_tools", "Close Gaps with Spline")`.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

## Not run:
# using SAGA grids:
rsaga.close.gaps("rawdem.sgrd", "dem.sgrd")
# using ASCII grids:
rsaga.esri.wrapper(rsaga.close.gaps, in.dem="rawdem", out.dem="dem")

## End(Not run)
```

rsaga.contour	<i>Contour Lines from a Grid</i>
---------------	----------------------------------

Description

Creates a contour lines shapefile from a grid file in SAGA grid format.

Usage

```
rsaga.contour(in.grid, out.shapefile, zstep, zmin, zmax, ...)
```

Arguments

in.grid	input: digital elevation model (DEM) as SAGA grid file (default file extension: .sgrd)
out.shapefile	output: contour line shapefile. Existing files will be overwritten!
zstep, zmin, zmax	lower limit, upper limit, and equidistance of contour lines
...	arguments to be passed to rsaga.geoprocessor

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

[rsaga.geoprocessor](#)

rsaga.env	<i>Set up the RSAGA Geoprocessing Environment</i>
-----------	---------------------------------------------------

Description

rsaga.env creates a list with system-dependent information on SAGA path, module path and data (working) directory. Such a list is required by all RSAGA geoprocessing functions.

Usage

```
rsaga.env( workspace=".",
  cmd = ifelse(.Platform$OS.type=="windows", "saga_cmd.exe", "saga_cmd"),
  path, modules, version, check.libpath = TRUE, check.SAGA = TRUE,
  check.PATH = .Platform$OS.type == "windows",
  check.os.default = TRUE,
  os.default.path = ifelse(.Platform$OS.type=="windows",
    "C:/Progra~1/SAGA-GIS",
    sub('/saga_cmd', '', system2('which', args='saga_cmd', stdout=TRUE))) )
```

Arguments

workspace	path of the working directory for SAGA; defaults to the current directory (".").
cmd	name of the SAGA command line program; defaults to saga_cmd.exe, its name under Windows
path	path in which to find cmd; rsaga.env is usually able to find SAGA on your system if it is installed; see Details.
modules	path in which to find SAGA libraries; see Details
version	optional character string: SAGA GIS (API) version, e.g. "2.0.8"; if missing, a call to rsaga.get.version is used to determine version number of SAGA API
check.libpath	if TRUE (default), first look for SAGA in the folder where the RSAGA package is installed
check.SAGA	if TRUE (default), next check the path given by the environment variable SAGA, if it exists
check.PATH	if TRUE (default on Windows), next look for SAGA in all the paths in the PATH environment variable; defaults to FALSE on non-Windows OS
check.os.default	if TRUE, look for SAGA in the folder specified by os.default.path.
os.default.path	under Windows, C:/Progra~1/SAGA-GIS; under unix, an attempt is made to locate saga_cmd

Details

IMPORTANT: Unlike R functions such as [options](#), which changes and saves settings somewhere in the background, [rsaga.env](#) does not actually 'save' any settings, it simply creates a list that can (and has to) be passed to other [rsaga.*](#) functions. See example below.

I strongly recommend to install SAGA GIS in "C:/Program Files/SAGA-GIS" in the case of English-language Windows platforms (the equivalent non-English installation folder in the case of non-English Windows versions seems to work as well). If this is the only SAGA GIS copy on the computer and you do *not* define a Windows environment variable SAGA, then RSAGA should normally be able to find your SAGA GIS installation.

[rsaga.env](#) tries to compile information on the (R)SAGA environment. If path is missing, [rsaga.env](#) first looks for an environment variable SAGA; if this is undefined, it checks the current working directory, then the paths given in the PATH environment variable, and finally the function's guess is "C:/Progra~1/SAGA-GIS" (or "/usr/local/bin" on non-Windows systems).

The default modules folder under Windows is the modules subfolder of the SAGA binaries' folder. The SAGA_MLB environment variable is *not* being checked by rsaga.env.

Under Unix, the default modules folder is as specified in the SAGA_MLB environment variable. If this is empty / not set, then the following backup path is used. If path ends with "/bin", then "/bin" is changed to "/lib/saga" and taken as the modules path; otherwise, /usr/local/lib/saga is used.

Value

A list with components workspace, cmd, path, and modules, with values as passed to rsaga.env or default values as described in the Details section.

Note

Note that the default workspace is ".", not getwd(); i.e. the default SAGA workspace folder is not fixed, it changes each time you change the R working directory using setwd.

[rsaga.get.version](#)

Examples

```
## Not run:
# Check the default RSAGA environment on your computer:
myenv <- rsaga.env()
myenv
# SAGA data in C:/sagadata, binaries in C:/SAGA-GIS, modules in C:/SAGA-GIS/modules:
myenv <- rsaga.env(workspace="C:/sagadata", path="C:/SAGA-GIS")
# Unix: SAGA in /usr/bin (instead of the default /usr/local/bin),
# and modules in /usr/lib/saga:
# myenv <- rsaga.env(path="/usr/bin")
# Use the 'myenv' environment for SAGA geoprocessing:
rsaga.hillshade("dem", "hillshade", env=myenv)
# ...creates (or overwrites) grid "C:/sagadata/hillshade.sgrd"
# derived from digital elevation model "C:/sagadata/dem.sgrd"

# Same calculation with different SAGA version:
# (I keep several versions in SAGA-GIS_2.0.x folders:)
myenv05 = rsaga.env(path = "C:/Progra~1/SAGA-GIS_2.0.5")
rsaga.hillshade("dem", "hillshade205", env=myenv05)

## End(Not run)
```

rsaga.esri.to.sgrd	<i>Convert ESRI ASCII/binary grids to SAGA grids</i>
--------------------	------------------------------------------------------

Description

rsaga.esri.to.sgrd converts grid files from ESRI's ASCII (.asc) and binary (.flt) format to SAGA's (version 2) grid format (.sgrd).

Usage

```
rsaga.esri.to.sgrd(in.grids, out.sgrds = set.file.extension(in.grids, ".sgrd"),
  in.path, ...)
```

Arguments

in.grids	character vector of ESRI ASCII/binary grid files (default file extension: .asc); files should be located in folder in.path
out.sgrds	character vector of output SAGA grid files; defaults to in.grids with file extension being replaced by .sgrd, which is also the default extension if file names without extension are specified; files will be placed in the current SAGA workspace (default: rsaga.env() \$workspace, or env\$workspace if an env argument is provided)
in.path	folder with in.grids
...	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

If multiple in.grids are converted, the result will be a vector of numerical error codes of the same length, or the combination of the console outputs with c().

Note

This function uses module 1 from the SAGA library io_grid.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

See Also

[rsaga.esri.wrapper](#) for an efficient way of applying RSAGA to ESRI ASCII/binary grids; [rsaga.env](#)

rsaga.esri.wrapper *Use RSAGA functions for ESRI grids*

Description

This wrapper converts input grid files provided in ESRI binary (.flt) or ASCII (.asc) formats to SAGA's (version 2) grid format, calls the RSAGA geoprocessing function, and converts the output grids back to the ESRI grid format. Conversion can also be limited to either input or output grids.

Usage

```
rsaga.esri.wrapper(fun, in.esri = TRUE, out.esri = TRUE, env = rsaga.env(),
  esri.workspace = env$workspace, format = "ascii", georef = "corner",
  prec = 5, esri.extension, condensed.res = TRUE, clean.up = TRUE,
  intern = TRUE, ...)
```

Arguments

fun	function: one of the RSAGA geoprocessing functions, such as rsaga.close.gaps or rsaga.hillshade etc.
in.esri	logical: are input grids provided as ESRI grids (in.esri=TRUE) or as SAGA grids?
out.esri	logical: should output grids be converted to ESRI grids?
env	RSAGA environment as returned by rsaga.env
esri.workspace	directory for the input and output ESRI ASCII/binary grids
format	output file format, either "ascii" (default; equivalent: format=1) for ASCII grids or "binary" (equivalent: 0) for binary ESRI grids (.flt).
georef	character: "corner" (equivalent numeric code: 0) or "center" (default; equivalent: 1). Determines whether the georeference will be related to the center or corner of its extreme lower left grid cell.
prec	number of digits when writing floating point values to ASCII grid files (only relevant if out.esri=TRUE)
esri.extension	extension for input/output ESRI grids: defaults to .asc for format="ascii", and to .flt for format="binary"
condensed.res	logical: return only results of the RSAGA geoprocessing function fun (condensed.res=TRUE), or include the results of the import and export operations, i.e. the calls to rsaga.esri.to.sgrd and rsaga.sgrd.to.esri ? (see Value)
clean.up	logical: delete intermediate SAGA grid files?
intern	intern argument to be passed to rsaga.geoprocessor ; see Value
...	additional arguments for fun; NOTE: ESRI ASCII/float raster file names should NOT include the file extension (.asc, .flt); the file extension is defined by the esri.extension and format arguments!

Details

ESRI ASCII/float raster file names should NOT include the file extension (.asc, .flt); the file extension is defined by the `esri.extension` and `format` arguments!

Value

The object returned depends on the `condensed.res` arguments and the `intern` argument passed to the [rsaga.geoprocessor](#).

If `condensed.res=TRUE` and `intern=FALSE`, a single numerical error code (0: success) is returned. If `condensed.res=TRUE` and `intern=TRUE` (default), a character vector with the module's console output is returned (invisibly).

If `condensed.res=FALSE` the result is a list with components `in.res`, `geoproc.res` and `out.res`. Each of these components is either an error code (for `intern=FALSE`) or (for `intern=TRUE`) a character vector with the console output of the input ([rsaga.esri.to.sgrd](#)), the geoprocessing (fun), and the output conversion ([rsaga.sgrd.to.esri](#)) step, respectively. For `in.esri=FALSE` or `out.esri=FALSE`, the corresponding component is `NULL`.

Note

Note that the intermediate grids as well as the output grids may overwrite existing files with the same file names without prompting the user. See example below.

Examples

```
## Not run:
rsaga.esri.wrapper(rsaga.hillshade,in.dem="dem",out.grid="hshd",condensed.res=FALSE,intern=FALSE)
# if successful, returns list(in.res=0,geoproc.res=0,out.res=0),
# and writes hshd.asc; intermediate files dem.sgrd, dem.hgrd, dem.sdat,
# hshd.sgrd, hshd.hgrd, and hshd.sdat are deleted.
# hshd.asc is overwritten if it already existed.

## End(Not run)
```

rsaga.fill.sinks *Fill Sinks*

Description

Several methods for filling closed depressions in digital elevation models that would affect hydrological modeling.

Usage

```
rsaga.fill.sinks(in.dem, out.dem, method = "planchon.darboux.2001",
                out.flowdir, out.wshed, minslope, ...)
```

Arguments

in.dem	Input: digital elevation model (DEM) as SAGA grid file (default extension: .sgrd).
out.dem	Output: filled, depression-free DEM (SAGA grid file). Existing files will be overwritten!
method	The depression filling algorithm to be used (character). One of "planchon.darboux.2001" (default), "wang.liu.2006", or "xxl.wang.liu.2006".
out.flowdir	(only for "wang.liu.2001"): Optional output grid file for computed flow directions (see Notes).
out.wshed	(only for "wang.liu.2001"): Optional output grid file for watershed basins.
minslope	Minimum slope angle (in degree) preserved between adjacent grid cells (default value of 0.01 only for method="planchon.darboux.2001", otherwise no default).
...	Optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment.

Details

This function bundles three SAGA modules for filling sinks using three different algorithms (method argument).

"planchon.darboux.2001": The algorithm of Planchon and Darboux (2001) consists of increasing the elevation of pixels in closed depressions until the sink disappears and a minimum slope angle of minslope (default: 0.01 degree) is established.

"wang.liu.2006": This module uses an algorithm proposed by Wang and Liu (2006) to identify and fill surface depressions in DEMs. The method was enhanced to allow the creation of hydrologically sound elevation models, i.e. not only to fill the depressions but also to preserve a downward slope along the flow path. If desired, this is accomplished by preserving a minimum slope gradient (and thus elevation difference) between cells. This is the fully featured version of the module creating a depression-free DEM, a flow path grid and a grid with watershed basins. If you encounter problems processing large data sets (e.g. LIDAR data) with this module try the basic version (xxl.wang.lui.2006).

"xxl.wang.liu.2006": This modified algorithm after Wang and Liu (2006) is designed to work on large data sets.

Value

The type of object returned depends on the `intern` argument passed to the `rsaga.geoprocessor`. For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

The function writes SAGA grid files containing of the depression-free preprocessed DEM, and optionally the flow directions and watershed basins.

Note

The flow directions are coded as 0 = north, 1 = northeast, 2 = east, ..., 7 = northwest.

If `minslope=0`, depressions will only be filled until a horizontal surface is established, which may not be helpful for hydrological modeling.

[rsaga.sink.removal](#), [rsaga.sink.route](#).

rsaga.filter.gauss	<i>Gauss Filter</i>
--------------------	---------------------

Description

Smooth a grid using a Gauss filter.

Usage

```
rsaga.filter.gauss(in.grid, out.grid, sigma,
  radius = ceiling(2 * sigma), ...)
```

Arguments

<code>in.grid</code>	input: SAGA grid file (default file extension: <code>.sgrd</code>)
<code>out.grid</code>	output: SAGA grid file
<code>sigma</code>	numeric, >0.0001 : standard deviation parameter of Gauss filter
<code>radius</code>	positive integer: radius of moving window
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 1 in the SAGA library `grid_filter`.

This SAGA module had a bug under 2.0.1 which has been corrected in version 2.0.2. (SAGA used to crash when this module was called.)

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

See Also

[rsaga.filter.simple](#)

`rsaga.filter.simple` *Simple Filters*

Description

Apply a smoothing, sharpening or edge filter to a SAGA grid.

Usage

```
rsaga.filter.simple(in.grid, out.grid, mode = "circle",
  method = c("smooth", "sharpen", "edge"), radius, ...)
```

Arguments

<code>in.grid</code>	input: SAGA grid file (default file extension: <code>.sgrd</code>)
<code>out.grid</code>	output: SAGA grid file
<code>mode</code>	character or numeric: shape of moving window, either "square" (=0) or "circle" (=1, default)
<code>method</code>	character or numeric: "smooth" (=0), "sharpen" (=1), or "edge" (=2)
<code>radius</code>	positive integer: radius of moving window
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

The `mode` argument is passed to SAGA as a `-MODE` command line option. This option used to be called `-SEARCH_MODE` under SAGA 2.0.1, so this function will cause an error under SAGA 2.0.1.

Note

This function uses module 0 in the SAGA library `grid_filter`.

## Not run: rsaga.filter.simple("dem","dem-smooth",radius=4)
```

rsaga.geoprocessor

Generic R interface for SAGA modules

Description

This function is the workhorse of the R–SAGA interface: It calls the SAGA command line tool to run SAGA modules and pass arguments.

Usage

```
rsaga.geoprocessor(lib, module = NULL, param = list(), prefix = NULL,
  silent = FALSE, beep.off, show.output.on.console = TRUE,
  invisible = TRUE, intern = TRUE, env = rsaga.env(), display.command = FALSE,
  reduce.intern=TRUE, check.module.exists = TRUE, warn = options("warn")$warn,
  ...)
```

Arguments

<code>lib</code>	Name of the SAGA library to be called (see Details).
<code>module</code>	Number (≥ 0) or name of the module to called within the library <code>lib</code> (see Details).
<code>param</code>	A list of named arguments to be passed to the SAGA module (see Examples).
<code>prefix</code>	optional character string: prefix such as "-h" used in the <code>saga_cmd</code> call; mostly for internal purposes; call <code>saga_cmd -h</code> from the command line for details
<code>silent</code>	(deprecated)
<code>beep.off</code>	is currently ignored (did never really work and produced some unwanted side effects); a warning is produced if <code>beep.off</code> is specified.
<code>show.output.on.console</code>	a logical (default: TRUE), indicates whether to capture the output of the command and show it on the R console (see system).
<code>invisible</code>	a logical, indicates whether the command window should be visible on the screen.
<code>intern</code>	a logical, indicates whether to make the output of the command an R object
<code>env</code>	A SAGA geoprocessing environment, i.e. currently a list with information on the SAGA and SAGA modules paths and the name of the working directory in which to look for input and output files. (Defaults: see rsaga.env .)
<code>display.command</code>	Display the DOS command line for executing the SAGA module (including all the arguments to be passed). Default: FALSE.
<code>reduce.intern</code>	If <code>intern=TRUE</code> , reduce the text output of SAGA returned to R by eliminating redundant lines showing the progress of module execution etc. (default: TRUE).
<code>check.module.exists</code>	logical (default: TRUE): call rsaga.module.exists to determine if the specified module can be called in the current SAGA installation
<code>warn</code>	logical (default: TRUE): for internal purposes - can be used to suppress warning messages generated by failed SAGA_CMD calls; currently used by rsaga.get.lib.modules and related functions; see options argument <code>warn</code> for details
<code>...</code>	Additional arguments to be passed to system .

Details

This workhorse function establishes the interface between the SAGA command line program and R by submitting a system call. This is a low-level function that may be used for directly accessing

SAGA; specific functions such as `rsaga.hillshade` are intended to be more user-friendly interfaces to the most frequently used SAGA modules. These higher-level interfaces support default values for the arguments and perform some error checking; they should therefore be preferred if available.

A warning is issued if the RSAGA version is not one of 2.0.4, 2.0.5, 2.0.6 or 2.0.7.

Value

The type of object returned depends on the `intern` argument passed to `system`.

If `intern=FALSE`, a numerical error/success code is returned, where a value of 0 corresponds to success and a non-zero value indicates an error. Note however that the function always returns a success value of 0 if `wait=FALSE`, i.e. if it does not wait for SAGA to finish.

If `intern=TRUE` (default), the console output of SAGA is returned as a character vector. This character vector lists the input file names and modules arguments, and gives a more or less detailed report of the function's progress. Redundant information can be cancelled out by setting `reduce.intern=TRUE`.

Note

Existing output files will be overwritten by SAGA without prompting!

If a terrain analysis function is not directly interfaced by one of the RSAGA functions, you might still find it in the growing set of SAGA libraries and modules. The names of all libraries available in your SAGA installation can be obtained using `rsaga.get.libraries` (or by checking the directory listing of the `modules` folder in the SAGA directory). The names and numeric codes of all available modules (globally or within a specific library) are retrieved by `rsaga.get.modules`. Full-text search in library and module names is performed by `rsaga.search.modules`. For information on the usage of SAGA command line modules, see `rsaga.get.usage`, or the RSAGA interface function if available.

`display.command=TRUE` is mainly intended for debugging purposes to check if all arguments are passed correctly to SAGA CMD.

Author(s)

Alexander Brenning (R interface); Olaf Conrad and the SAGA development team (SAGA development)

`rsaga.env`, `rsaga.get.libraries`, `rsaga.get.modules`, `rsaga.search.modules`, `rsaga.get.usage`; `rsaga.esri.wrapper` for a wrapper for ESRI ASCII/binary grids; `rsaga.hillshade` and other higher-level functions.

Examples

```
## Not run:
rsaga.hillshade("dem", "hillshade", exaggeration=2)
# using the RSAGA geoprocessor:
rsaga.geoprocessor("ta_lighting", 0, list(ELEVATION="dem.sgrd", SHADE="hillshade", EXAGGERATION=2))
```

```
# equivalent DOS command line call:
# saga_cmd.exe ta_lighting 0 -silent -ELEVATION dem.sgrd -SHADE hillshade -EXAGGERATION 2

## End(Not run)
```

rsaga.get.modules *Find SAGA libraries and modules*

Description

These functions list the SAGA libraries (`rsaga.get.libraries`) and modules (`rsaga.get.lib.modules`, `rsaga.get.modules`) available in a SAGA installation, and allow to perform a full-text search among these functions.

Usage

```
rsaga.get.libraries(path = rsaga.env())$modules,
  dll = .Platform$dynlib.ext)
rsaga.get.lib.modules(lib, env = rsaga.env(), interactive = FALSE)
rsaga.get.modules(libs, env = rsaga.env(), ...)
rsaga.search.modules(text, modules, search.libs = TRUE,
  search.modules = TRUE, env = rsaga.env(),
  ignore.case = TRUE, ...)
rsaga.module.exists(libs, module, env = rsaga.env(), ...)
```

Arguments

text	character string to be searched for in the names of available libraries and/or modules
search.libs, search.modules	logical (default TRUE: should text be searched for in library and/or module names?
ignore.case	logical (default FALSE): should the text search in library/module names be case sensitive?
lib, libs	character vector (libs) or character string (lib) with the name(s) of library/ies in which to look for modules; if libs is missing, all libraries will be processed
module	module name or numeric code
modules	optional list: result of <code>rsaga.get.modules</code> ; if missing, a list of available modules will be retrieved using that function
env	list, setting up a SAGA geoprocessing environment as created by rsaga.env
path	path of SAGA library files (modules subfolder in the SAGA installation folder); defaults to the path determined by rsaga.env .
dll	file extension of dynamic link libraries
interactive	logical (default FALSE): should modules be returned that can only be executed in interactive mode (i.e. using SAGA GUI)?
...	currently only interactive to be passed on to <code>rsaga.get.lib.modules</code>

Value

`rsaga.get.libraries` returns a character vector with the names of all SAGA libraries available in the folder `env$modules`.

`rsaga.get.lib.modules` returns a `data.frame` with:

<code>name</code>	the names of all modules in library <code>lib</code> ,
<code>code</code>	their numeric identifiers,
<code>interactive</code>	and a logical variable indicating whether a module can only be executed in interactive (SAGA GUI) mode.

`rsaga.get.modules` returns a list with, for each SAGA library in `libs`, a `data.frame` with module information as given by `rsaga.get.lib.modules`. If `libs` is missing, all modules in all libraries will be retrieved.

Note

For information on the usage of SAGA command line modules, see [rsaga.get.usage](#) (or [rsaga.html.help](#)), or the RSAGA interface function, if available.

Examples

```
## Not run:
# make sure that 'rsaga.env' can find 'saga_cmd.exe'
# before running this:
rsaga.get.libraries()
# list all modules in my favorite libraries:
rsaga.get.modules(c("io_grid", "grid_tools", "ta_preprocessor",
  "ta_morphometry", "ta_lighting", "ta_hydrology"))
# list *all* modules (quite a few!):
# rsaga.get.modules(interactive=TRUE)

# find modules that remove sink from DEMs:
rsaga.search.modules("sink")
# find modules that close gaps (no-data areas) in grids:
rsaga.search.modules("gap")

## End(Not run)
```

rsaga.get.usage	<i>Usage of SAGA command line modules</i>
-----------------	-------------------------------------------

Description

rsaga.get.usage provides information on the usage of and arguments required by SAGA command line modules.

Usage

```
rsaga.get.usage(lib, module, env = rsaga.env(), show = TRUE)
```

Arguments

lib	name of the SAGA library
module	name or numeric identifier of SAGA module in library lib
env	list, setting up a SAGA geoprocessing environment as created by rsaga.env
show	logical (default: TRUE; display usage on R console?)

Details

This function is intended to provide information required to use the [rsaga.geoprocessor](#) and for writing your own high-level interface function for SAGA modules. R-SAGA interfaces already exist for some SAGA modules, e.g. [rsaga.hillshade](#), [rsaga.local.morphometry](#). For information on the usage and arguments

Value

The character vector with usage information is invisibly returned.

Author(s)

Alexander Brenning

Examples

```
## Not run:
rsaga.get.usage("io_grid",1)
rsaga.get.usage("ta_preprocessor",2)
rsaga.get.usage("ta_morphometry",0)

## End(Not run)
```

rsaga.get.version	<i>Determine SAGA GIS version</i>
-------------------	-----------------------------------

Description

Determine SAGA GIS version.

Usage

```
rsaga.get.version(env = rsaga.env(version=NA), ...)
```

Arguments

env	list, setting up a SAGA geoprocessing environment as created by rsaga.env . Note that version=NA ensures that rsaga.env won't call rsaga.get.version itself.
...	additional arguments to rsaga.geoprocessor

Details

The function first attempts to determine the SAGA version directly through a system call `saga_cmd --version`, which is supported by SAGA GIS 2.0.8. If this fails, `saga_cmd -h` is called, and it is attempted to extract the version number of the SAGA API from the output generated, which works for 2.0.4+.

Value

A character string defining the SAGA GIS (API) version. E.g., "2.0.8".

Author(s)

Alexander Brenning

See Also

[rsaga.env](#)

Examples

```
## Not run:
myenv <- rsaga.env()
myenv$version
# rsaga.env actually calls rsaga.get.version:
rsaga.get.version()

# I keep several versions of SAGA GIS in SAGA-GIS_2.0.x folders:
myenv05 = rsaga.env(path = "C:/Progra~1/SAGA-GIS_2.0.5", version = NA)
# Check if it's really version 2.0.5 as suggested by the folder name:
rsaga.get.version(env = myenv05)

## End(Not run)
```

rsaga.grid.calculus *SAGA Module Grid Calculus*

Description

Perform Arithmetic Operations on Grids

Usage

```
rsaga.grid.calculus(in.grids, out.grid, formula,
                    env = rsaga.env(), ...)
rsaga.linear.combination(in.grids, out.grid,
                        coef, cf.digits = 16, remove.zeros = FALSE,
                        remove.ones = TRUE, env = rsaga.env(), ...)
```

Arguments

<code>in.grids</code>	input character vector: SAGA grid files (default file extension: <code>.sgrd</code>)
<code>out.grid</code>	output: grid file resulting from the cell-by-cell application of 'formula' to the grids. Existing files will be overwritten!
<code>formula</code>	character string of formula specifying the arithmetic operation to be performed on the <code>in.grids</code> (see Details); if this is a formula, only the right hand side will be used.
<code>coef</code>	numeric: coefficient vector to be used for the linear combination of the <code>in.grids</code> . If <code>coef</code> as one more element than <code>in.grids</code> , the first one will be interpreted as an intercept.
<code>cf.digits</code>	integer: number of digits used when converting the coefficients to character strings (trailing zeros will be removed)
<code>remove.zeros</code>	logical: if TRUE, terms (grids) with coefficient (numerically) equal to zero (after rounding to <code>cf.digits</code> digits) will be removed from the formula
<code>remove.ones</code>	logical: if TRUE (default), factors equal to 1 (after rounding to <code>cf.digits</code> digits) will be removed from the formula
<code>env</code>	character string, either '2.0.4' (default) or '2.0.5'; the command line arguments for the grid calculator module changed from SAGA GIS 2.0.4 to 2.0.5, the function is now able to handle both situations; if using a different SAGA GIS version, try one of these two options, or look at <code>rsaga.get.usage</code> and use <code>rsaga.geoprocessor</code> directly; sorry for the inconvenience
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor , including the <code>env</code> RSAGA geoprocessing environment

Details

The `in.grids` are represented in the formula by the letters `a` (for `in.grids[1]`), `b` etc. Thus, if `in.grids[1]` is Landsat TM channel 3 and `in.grids[2]` is channel 4, the NDVI formula $(TM3 - TM4) / (TM3 + TM4)$ can be represented by the character string "`(a-b)/(a+b)`" (any spaces are removed) or the formula `~(a-b)/(a+b)` in the formula argument.

In addition to `+`, `-`, `*`, and `/`, the following operators and functions are available for the formula definition:

- `^`power
- `sin(a)`sine
- `cos(a)`cosine
- `tan(a)`tangent
- `asin(a)`arc sine
- `acos(a)`arc cosine
- `atan(a)`arc tangent
- `atan2(a,b)`arc tangent of `b/a`
- `abs(a)`absolute value
- `int(a)`convert to integer
- `sqrt(a)`square root
- `ln(a)`natural logarithm
- `mod(a,b)`modulo
- `gt(a, b)`returns 1 if `a` greater `b`
- `lt(a, b)`returns 1 if `a` lower `b`
- `eq(a, b)`returns 1 if `a` equal `b`
- `ifelse(switch, x, y)`returns `x` if `switch` equals 1 else `y`

Using `remove.zeros=FALSE` might have the side effect that no data areas in the grid with coefficient 0 are passed on to the results grid. (To be confirmed.)

Value

The type of object returned depends on the `intern` argument passed to the `rsaga.geoprocessor`. For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 1 in the SAGA library `grid_calculus`.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

See Also

[local.function](#), [focal.function](#), and [multi.focal.function](#) for a more flexible framework for combining grids or applying local and focal functions; [rsaga.geoprocessor](#), [rsaga.env](#)

Examples

```
## Not run:
# using SAGA grids:
# calculate the NDVI from Landsat TM bands 3 and 4:
rsaga.grid.calculus(c("tm3.sgrd","tm4.sgrd"), "ndvi.sgrd", ~(a-b)/(a+b))
# apply a linear regression equation to grids:
coefs = c(20,-0.6)
# maybe from a linear regression of mean annual air temperature (MAAT)
# against elevation - something like:
# coefs = coef( lm( maat ~ elevation ) )
rsaga.linear.combination("elevation.sgrd", "maat.sgrd", coefs)
# equivalent:
rsaga.grid.calculus("elevation.sgrd", "maat.sgrd", ~ 20 - 0.6*a)

## End(Not run)
```

rsaga.grid.to.points *Convert SAGA grid file to point shapefile*

Description

Convert SAGA grid file to point (or polygon) shapefile - either completely or only a random sample of grid cells.

Usage

```
rsaga.grid.to.points(in.grids, out.shapefile,
  in.clip.polygons, exclude.nodata = TRUE,
  type = "nodes", env = rsaga.env(), ...)
rsaga.grid.to.points.randomly(in.grid, out.shapefile, freq, ...)
```

Arguments

in.grids	Input: names of (possibly several) SAGA grid files to be converted into a point shapefile.
in.grid	Input: SAGA grid file from which to sample.
out.shapefile	Output: point shapefile (default extension: .shp). Existing files will be overwritten!
in.clip.polygons	optional polygon shapefile to be used for clipping/masking an area
exclude.nodata	logical (default: TRUE): skip 'nodata' grid cells?

type	character string: "nodes": create point shapefile of grid center points; "cells" (only supported by SAGA GIS 2.0.6+): create polygon shapefile with grid cell boundaries
freq	integer >=1: sampling frequency: on average 1 out of 'freq' grid cells are selected
env	RSAGA geoprocessing environment created by rsaga.env ; required by rsaga.grid.to.points to determine version-dependent SAGA module name and arguments
...	Optional arguments to be passed to rsaga.geoprocessor

Note

These functions use modules Grid Values to Shapes (code: 3; pre-2.0.6 name: Grid Values to Points) and Grid Values to Points (randomly) (code: 4) in SAGA library shapes_grid.

The SAGA 2.0.6+ module Grid Values to Shapes is more flexible than the earlier versions as it allows to create grid cell polygons instead of center points (see argument type).

[rsaga.add.grid.values.to.points](#)

Examples

```
## Not run:
# one point per grid cell, exclude nodata areas:
rsaga.grid.to.points("dem", "dempoints")
# take only every 20th point, but to not exclude nodata areas:
rsaga.grid.to.points.randomly("dem", "dempoints20", freq = 20)

## End(Not run)
```

rsaga.hillshade

Analytical hillshading

Description

Analytical hillshading calculation.

Usage

```
rsaga.hillshade(in.dem, out.grid, method = "standard",
  azimuth = 315, declination = 45, exaggeration = 4, ...)
```

Arguments

<code>in.dem</code>	Input digital elevation model (DEM) as SAGA grid file (default extension: <code>.sgrd</code>).
<code>out.grid</code>	Output hillshading grid (SAGA grid file). Existing files will be overwritten!
<code>method</code>	Available choices (character or numeric): "standard" (or 0 - default), "max90deg.standard" (1), "combined.shading" (2), "ray.tracing" (3). See Details.
<code>azimuth</code>	Direction of the light source, measured in degree clockwise from the north direction; default 315, i.e. northwest.
<code>declination</code>	Declination of the light source, measured in degree above the horizon (default 45).
<code>exaggeration</code>	Vertical exaggeration of elevation (default: 4). The terrain exaggeration factor allows to increase the shading contrasts in flat areas.
<code>...</code>	Optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment.

Details

The Analytical Hillshading algorithm is based on the angle between the surface and the incoming light beams, measured in radians.

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

While the default azimuth of 315 degree (northwest) is not physically meaningful on the northern hemisphere, a northwesterly light source is required to properly depict relief in hillshading images. Physically correct southerly light sources results a hillshade that would be considered by most people as inverted: hills look like depressions, mountain chains like troughs.

This function uses module 0 from SAGA library `ta_lighting`.

## Not run: rsaga.hillshade("dem.sgrd","hillshade")
```

rsaga.html.help *HTML help on a SAGA module or library*

Description

This function tries to obtain SAGA's HTML help for the specified library or module. NOTE: HTML help files are not provided with all SAGA distributions.

Usage

```
rsaga.html.help(lib, module, env = rsaga.env(), ...)
```

Arguments

lib	name of the SAGA library, or one of the rsaga. module functions such as rsaga.hillshade
module	name or numeric identifier of SAGA module in library lib; module=NULL links to the main help page of the SAGA library lib
env	list, setting up a SAGA geoprocessing environment as created by rsaga.env
...	additional arguments

Details

Doesn't seem to work with SAGA GIS 2.0.2+, needs to be updated, sorry. Please use [rsaga.get.usage](#) or [rsaga.search.modules](#) or [rsaga.get.modules](#) instead. This function is currently only kept as a place holder for future referencing of SAGA GIS Wiki pages that are currently under development.

rsaga.import.gdal *Import Grid Files to SAGA grid format using GDAL*

Description

These functions provide simple interfaces for reading and writing grids from/to ASCII grids and Rd files. Grids are stored in matrices, their headers in lists.

Usage

```
rsaga.import.gdal(in.grid, out.grid, env = rsaga.env(), ...)
```

Arguments

<code>in.grid</code>	file name of a grid in a format supported by GDAL
<code>out.grid</code>	output SAGA grid file name; defaults to <code>in.grid</code> with the file extension being removed; file extension should not be specified, it defaults to <code>.sgrd</code>
<code>env</code>	RSAGA geoprocessing environment created by rsaga.env
<code>...</code>	additional arguments to be passed to <code>rsaga.geoprocessor</code>

Details

The GDAL Raster Import module of SAGA imports grid data from various file formats using the Geospatial Data Abstraction Library (GDAL) by Frank Warmerdam. As of SAGA GIS 2.0.7, GDAL version 1.8.0 is used. More information is available at <http://www.gdal.org/>.

If `in.grid` has more than one band (e.g. RGB GEOTIFF), then output grids with file names of the form `in.grid_01.sgrd`, `in.grid_02.sgrd` etc. are written, one for each band.

The following raster formats are currently supported (SAGA GIS 2.0.7):

- VRTVirtual Raster
- GTiffGeoTIFF
- NITFNational Imagery Transmission Format
- RPFTOCRaster Product Format TOC format
- HFAErdas Imagine Images (.img)
- SAR_CEOSCEOS SAR Image
- CEOSCEOS Image
- JAXAPALSARJAXA PALSAR Product Reader (Level 1.1/1.5)
- GFFGround-based SAR Applications Testbed File Format (.gff)
- ELASELAS
- AIGArc/Info Binary Grid
- AAIGridArc/Info ASCII Grid
- SDTSSDTS Raster
- DTEDDTED Elevation Raster
- PNGPortable Network Graphics
- JPEGJPEG JFIF
- MEMIn Memory Raster
- JDEMJapanese DEM (.mem)
- GIFGraphics Interchange Format (.gif)
- BIGGIFGraphics Interchange Format (.gif)
- ESATEnvisat Image Format

rsaga.insolation	<i>Incoming Solar Radiation (Insolation)</i>
------------------	----------------------------------------------

Description

This function calculates the amount of incoming solar radiation (insolation) depending on slope, aspect, and atmospheric properties. Module not available in SAGA GIS 2.0.6 and 2.0.7.

Usage

```
rsaga.insolation(in.dem, in.vapour, in.latitude, in.longitude,
  out.direct, out.diffuse, out.total, horizontal = FALSE,
  solconst = 8.164, atmosphere = 12000, water.vapour.pressure = 10,
  type = c("moment", "day", "range.of.days", "same.moment.range.of.days"),
  time.step = 1, day.step = 5, days, moment, latitude, bending = FALSE,
  radius = 6366737.96, lat.offset = "user", lat.ref.user = 0,
  lon.offset = "center", lon.ref.user = 0, ...)
```

Arguments

in.dem	Name of input digital elevation model (DEM) grid in SAGA grid format (default extension: .sgrd)
in.vapour	Optional input: SAGA grid file giving the water vapour pressure in mbar
in.latitude	Optional input: SAGA grid file giving for each pixel the latitude in degree
in.longitude	Optional input: SAGA grid file giving for each pixel the longitude in degree
out.direct	Optional output grid file for direct insolation
out.diffuse	Optional output grid file for diffuse insolation
out.total	Optional output grid file for total insolation, i.e. the sum of direct and diffuse insolation
horizontal	logical; project radiation onto a horizontal surface? (default: FALSE, i.e. use the actual inclined surface as a reference area)
solconst	solar constant in Joule; default: 8.164 J/cm ² /min (=1360.7 kWh/m ² ; the more commonly used solar constant of 1367 kWh/m ² corresponds to 8.202 J/cm ² /min)
atmosphere	height of atmosphere in m; default: 12000m
water.vapour.pressure	if no water vapour grid is given, this argument specifies a constant water vapour pressure that is uniform in space; in mbar, default 10 mbar
type	type of time period: "moment" (equivalent: 0) for a single instant, "day" (or 1) for a single day, "range.of.days" (or 2), or "same.moment.range.of.days" (or 3) for the same moment in a range of days; default: "moment"
time.step	time resolution in hours for discretization within a day
day.step	time resolution in days for a range of days

days	numeric vector of length 2, specifying the first and last day of a range of days (for types 2 and 3)
moment	if type="moment" or "same.moment.range.of.days", moment specifies the time of the day (hour between 0 and 24) for which the insolation is to be calculated
latitude	if no in.latitude grid is given, this will specify a fixed geographical latitude for the entire grid
bending	should planetary bending be modeled? (default: FALSE)
radius	planetary radius
lat.offset	latitude relates to grids "bottom" (equivalent code: 0), "center" (1), "top" (2), or "user"-defined reference (default: "user"); in the latter case, lat.ref.user defines the reference
lat.ref.user	if in.latitude is missing and lat.offset="user", then this numeric value defines the latitudinal reference (details??)
lon.offset	local time refers to grid's "left" edge (code 0), "center" (1), "right" edge (2), or a "user"-defined reference.
lon.ref.user	if in.longitude is missing and lon.offset="user", then this numeric value defines the reference of the local time (details??)
...	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Details

Calculation of incoming solar radiation (insolation). Based on the SADO (System for the Analysis of Discrete Surfaces) routines developed by Boehner & Trachinow.

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module Insolation (code: 3) from SAGA library ta_lighting. It is available in SAGA GIS 2.0.4 and 2.0.5 but not 2.0.6 and 2.0.7; see [rsaga.pisr](#).

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

rsaga.inverse.distance

Spatial Interpolation Methods

Description

Spatial interpolation of point data using inverse distance to a power (inverse distance weighting, IDW), nearest neighbors, or modified quadratic shephard.

Usage

```
rsaga.inverse.distance(in.shapefile, out.grid, field,
                      power = 1, maxdist = 100, nmax = 10,
                      target = rsaga.target(), env = rsaga.env(), ...)
rsaga.nearest.neighbour(in.shapefile, out.grid, field,
                       target = rsaga.target(), env = rsaga.env(), ...)
rsaga.modified.quadratic.shephard(in.shapefile, out.grid, field,
                                  quadratic.neighbors = 13, weighting.neighbors = 19,
                                  target = rsaga.target(), env = rsaga.env(), ...)
```

Arguments

in.shapefile	Input: point shapefile (default extension: .shp).
out.grid	Output: filename for interpolated grid (SAGA grid file). Existing files will be overwritten!
field	numeric(!): number (not name!) of attribute in the shapefile's attribute table to be interpolated; the first attribute is represented by a zero.
power	numeric (>0): exponent used in inverse distance weighting (usually 1 or 2)
maxdist	numeric: maximum distance of points to be used for inverse distance interpolation (search radius)
nmax	Maximum number of nearest points to be used for interpolation
quadratic.neighbors	integer >=5; ??
weighting.neighbors	integer >=3; ??
target	list: parameters identifying the target area, e.g. the lower left corner and size of grid, or name of a reference grid; see rsaga.target .
env	RSAGA geoprocessing environment created by rsaga.env , required because module(s) depend(s) on SAGA version
...	Optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment.

Details

Inverse distance weighting (IDW) uses module 0 in the SAGA library `grid_gridding`. Nearest neighbour interpolation uses module 1, and triangulation is performed by module 4.

Note

The 'Inverse Distance Weighted' module of SAGA GIS (library 'grid_gridding') has changed from SAGA GIS 2.0.4 to 2.0.5. The module now not only support inverse-distance weighted interpolation, but also exponential and other weighting schemes (command line argument `WEIGHTING`); these are however not accessible through this function, but only through the `rsaga.geoprocessor`. See `rsaga.get.usage("grid_gridding", "Inverse Distance Weighted")` for details. This R function furthermore only interfaces the local version of IDW, which uses a local search radius (argument 'radius'); the SAGA module now (2.0.5) also supports global IDW.

See the example section in the help file for `write.shapefile` in package `shapefiles` to learn how to apply these interpolation functions to a shapefile exported from a `data.frame`.

Modified Quadratic Shephard method: based on module 660 in TOMS (see references).

Author(s)

Alexander Brenning (R interface), Andre Ringeler and Olaf Conrad (SAGA modules)

rsaga.local.morphometry

Local Morphometry

Description

Calculates local morphometric terrain attributes (i.e. slope, aspect and curvatures).

Usage

```
rsaga.local.morphometry(in.dem, out.slope, out.aspect, out.curv,
  out.hcurv, out.vcurv, method = "poly2zevenbergen",
  env = rsaga.env(), ...)
rsaga.slope(in.dem, out.slope, method = "poly2zevenbergen", ...)
rsaga.aspect(in.dem, out.aspect, method = "poly2zevenbergen", ...)
rsaga.curvature(in.dem, out.curv, method = "poly2zevenbergen", ...)
```

```
rsaga.plan.curvature(in.dem, out.hcurv, method = "poly2zevenbergen", ...)
rsaga.profile.curvature(in.dem, out.vcurv, method = "poly2zevenbergen", ...)
```

Arguments

<code>in.dem</code>	input: digital elevation model (DEM) as SAGA grid file (default file extension: <code>.sgrd</code>)
<code>out.slope</code>	optional output: slope (in radian)
<code>out.aspect</code>	optional output: aspect (in radian; north=0, clockwise angles)
<code>out.curv</code>	optional output: curvature
<code>out.hcurv</code>	optional output: horizontal curvature (plan curvature)
<code>out.vcurv</code>	optional output: vertical curvature (profile curvature)
<code>method</code>	character or numeric: algorithm (see References): Maximum Slope - Travis et al. (1975) ("maxslope", or 0), Max. Triangle Slope - Tarboton (1997) ("maxtriangleslope", or 1), Least Squares Fit Plane - Costa-Cabral and Burgess (1996) ("lsqfitplane", or 2), Fit 2nd Degree Polynomial - Bauer et al. (1985) ("poly2bauer", or 3), Fit 2nd Degree Polynomial - Heerdegen and Beran (1982) ("poly2heerdegen", or 4), default: Fit 2nd Degree Polynomial - Zevenbergen and Thorne (1987) ("poly2zevenbergen", or 5), Fit 3rd Degree Polynomial - Haralick (1983) ("poly3haralick", or 6).
<code>env</code>	list, setting up a SAGA geoprocessing environment as created by rsaga.env
<code>...</code>	further arguments to rsaga.geoprocessor

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 0 from the SAGA library `ta_morphometry`.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

## End(Not run)
```

rsaga.ordinary.kriging

Local Ordinary Kriging

Description

Perform ordinary kriging using a local search neighborhood (local ordinary kriging). Also supports block kriging.

Usage

```
rsaga.ordinary.kriging(in.shapefile, out.grid,
  out.variance.grid, field,
  model = c("spherical", "exponential", "gaussian"),
  nugget = 0, sill = 10, range = 100,
  log.transform = FALSE, maxdist = 1000, blocksize,
  nmin = 4, nmax = 20, target = rsaga.target(),
  env = rsaga.env(), ...)
```

Arguments

<code>in.shapefile</code>	Input: point shapefile (default extension: .shp).
<code>out.grid</code>	Output: filename for interpolated grid (SAGA grid file). Existing files will be overwritten!
<code>out.variance.grid</code>	Output (optional): SAGA grid for kriging variances
<code>field</code>	numeric(!): number (not name!) of attribute in the shapefile's attribute table to be interpolated; the first attribute is represented by a zero.
<code>model</code>	character: variogram model to be used; defaults to "spherical".
<code>nugget</code>	numeric (≥ 0): Nugget effect
<code>sill</code>	numeric (≥ 0): Sill of the variogram
<code>range</code>	numeric (≥ 0): Variogram range
<code>log.transform</code>	logical: apply a log transformation to the observations? (default: FALSE).
<code>maxdist</code>	numeric: maximum distance of nearest points to be used for kriging (search radius)
<code>nmin</code>	numeric: Minimum number of points (within the local search neighborhood) required for interpolation.
<code>nmax</code>	numeric: Maximum number of nearest points to be used for interpolation
<code>blocksize</code>	numeric: block size for block kriging; block kriging is applied if this parameter is specified. If blocksize is missing (default), ordinary (point) kriging is used.
<code>target</code>	list: parameters identifying the target area, e.g. the lower left corner and size of grid, or name of a reference grid; see rsaga.target .
<code>env</code>	RSAGA geoprocessing environment created by rsaga.env , required because module(s) depend(s) on SAGA version
<code>...</code>	Optional arguments to be passed to rsaga.geoprocessor .

Note

This function uses module 4 ("Ordinary Kriging") in SAGA library `grid_gridding` (users of the GUI of SAGA GIS should not be confused by the fact that the "Ordinary Kriging" module appears first in the GUI's module listing - it is in fact module 4).

The SAGA module support some other variogram models(?), but I am not quite sure what they are doing, so they (and the associated additional parameters) are currently not supported by this wrapper function. The module's usage page also mentions a `FORMULA` argument, but this seems to be a mistake.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

Examples

```
## Not run:
# Krige attribute 0 from the points shapefile to
# a grid with the same extent and resolutionn as the
# (pre-existing) geology grid:
rsaga.ordinary.kriging("points", "dem", field = 0, maxdist = 1000,
  target = rsaga.target(target="target.grid",
    target.grid = "geology"))
# Specify a target grid manually (see rsaga.target):
rsaga.ordinary.kriging("points", "dem", field = 0, radius = 1000,
  target = rsaga.target("grid.system",
    system.nx = 200, system.ny = 300,
    system.xy = c(604853,7465013), system.d = 50))

## End(Not run)
```

rsaga.parallel.processing

Parallel Processing

Description

Calculate the size of the local catchment area (contributing area), the catchment height, catchment slope and aspect, and flow path length, using parallel processing algorithms including the recommended multiple flow direction algorithm. This set of algorithms processes a digital elevation model (DEM) downwards from the highest to the lowest cell.

Usage

```
rsaga.parallel.processing(in.dem, in.sinkroute, in.weight,
  out.carea, out.cheight, out.cslope, out.caspect, out.flowpath,
  step, method = "mfd", linear.threshold = Inf,
  convergence = 1.1, env = rsaga.env(), ...)
```

Arguments

in.dem	input: digital elevation model (DEM) as SAGA grid file (default file extension: .sgrd)
in.sinkroute	optional input: SAGA grid with sink routes
in.weight	optional input: SAGA grid with weights

<code>out.carea</code>	output: catchment area grid
<code>out.cheight</code>	optional output: catchment height grid
<code>out.cslope</code>	optional output: catchment slope grid
<code>out.caspect</code>	optional output: catchment aspect grid
<code>out.flowpath</code>	optional output: flow path length grid
<code>step</code>	integer ≥ 1 : step parameter
<code>method</code>	character or numeric: choice of processing algorithm: Deterministic 8 ("d8" or 0), Rho 8 ("rho8" or 1), Braunschweiger Reliefmodell ("braunschweig" or 2), Deterministic Infinity ("dinf" or 3), Multiple Flow Direction ("mfd" or 4, default), Multiple Triangular Flow Direction ("mtfd", or 5).
<code>linear.threshold</code>	numeric (number of grid cells): threshold above which linear flow (i.e. the Deterministic 8 algorithm) will be used; linear flow is disabled for <code>linear.threshold=Inf</code> (default)
<code>convergence</code>	numeric ≥ 0 : a parameter for tuning convergent/ divergent flow; default value of 1.1 gives realistic results and should not be changed
<code>env</code>	list, setting up a SAGA geoprocessing environment as created by rsaga.env
<code>...</code>	further arguments to rsaga.geoprocessor

Details

Refer to the references for details on the available algorithms.

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module Parallel Processing (version 2.0.7: Catchment Area (Parallel) from SAGA library `ta_hydrology`.

The SAGA GIS 2.0.6+ version of the module adds more (optional) input and output grids that are currently not supported by this wrapper function. Use [rsaga.geoprocessor](#) for access to these options, and see `rsaga.get.usage("ta_hydrology", "Catchment Area (Parallel)")` for information on new arguments.

```

rsaga.pisr

*Potential incoming solar radiation***Description**

This function calculates the potential incoming solar radiation in an area using different atmospheric models; module available in SAGA GIS 2.0.6+.

Usage

```
rsaga.pisr(in.dem, in.svf.grid = NULL, in.vapour.grid = NULL,
  in.latitude.grid = NULL, in.longitude.grid = NULL,
  out.direct.grid, out.diffuse.grid, out.total.grid = NULL,
  out.ratio.grid = NULL, out.duration, out.sunrise, out.sunset,
  local.svf = TRUE, latitude,
  unit=c("kWh/m2", "kJ/m2", "J/cm2"), solconst=1367.0,
  enable.bending = FALSE, bending.radius = 6366737.96,
  bending.lat.offset = "user", bending.lat.ref.user = 0,
  bending.lon.offset = "center", bending.lon.ref.user = 0,
  method = c("height", "components", "lumped"),
  hgt.atmosphere = 12000, hgt.water.vapour.pressure = 10,
  cmp.pressure = 1013, cmp.water.content = 1.68, cmp.dust = 100,
  lmp.transmittance = 70,
  time.range = c(0,24), time.step = 0.5,
  start.date = list(day=21, month=3), end.date = NULL, day.step = 5,
  env = rsaga.env(), ...)
```

Arguments

in.dem	name of input digital elevation model (DEM) grid in SAGA grid format (default extension: .sgrd)
in.svf.grid	Optional input grid in SAGA format: Sky View Factor; see also local.svf
in.vapour.grid	Optional input grid in SAGA format: Water vapour pressure (mbar); see also argument hgt.water.vapour.pressure
in.latitude.grid	Optional input grid in SAGA format: Latitude (degree) of each grid cell
in.longitude.grid	see in.latitude.grid
out.direct.grid	Output grid: Direct insolation (unit selected by unit argument)
out.diffuse.grid	Output grid: Diffuse insolation
out.total.grid	Optional output grid: Total insolation, i.e. sum of direct and diffuse incoming solar radiation
out.ratio.grid	Optional output grid: Direct to diffuse ratio

<code>out.duration</code>	Optional output grid: Duration of insolation
<code>out.sunrise</code>	Optional output grid: time of sunrise; only calculated if time span is set to single day
<code>out.sunset</code>	Time of sunset; see <code>out.sunrise</code>
<code>local.svf</code>	logical (default: TRUE; if TRUE, use sky view factor based on local slope (after Oke, 1988), if no sky view factor grid is provided in <code>in.svf.grid</code>
<code>latitude</code>	Geographical latitude in degree North (negative values indicate southern hemisphere)
<code>unit</code>	unit of insolation output grids: "kWh/m2" (default) "kJ/m2", or "J/cm2"
<code>solconst</code>	solar constant, defaults to 1367 W/m2
<code>enable.bending</code>	logical (default: FALSE): incorporate effects of planetary bending?
<code>bending.radius</code>	Planetary radius, default 6366737.96
<code>bending.lat.offset</code>	if bending is enabled: latitudinal reference is "user"-defined (default), or relative to "top", "center" or "bottom" of grid?
<code>bending.lat.ref.user</code>	user-defined lat. reference for bending, see <code>bending.lat.offset</code>
<code>bending.lon.offset</code>	longitudinal reference, i.e. local time, is "user"-defined, or relative to "top", "center" (default) or "bottom" of grid?
<code>bending.lon.ref.user</code>	user-defined reference for local time (Details??)
<code>method</code>	specifies how the atmospheric components should be accounted for: either based on the height of atmosphere and vapour pressure ("height", or numeric code 0), or air pressure, water and dust content ("components", code 1), or lumped atmospheric transmittance ("lumped", code 0)
<code>hgt.atmosphere</code>	Height of atmosphere (in m); default 12000 m
<code>hgt.water.vapour.pressure</code>	Water vapour pressure in mbar (default 10 mbar); This value is used if no vapour pressure grid is given in argument <code>in.vapour.grid</code>
<code>cmp.pressure</code>	atmospheric pressure in mbar, defaults to 1013 mbar
<code>cmp.water.content</code>	water content of a vertical slice of the atmosphere in cm: between 1.5 and 1.7cm, average 1.68cm (default)
<code>cmp.dust</code>	dust factor in ppm; defaults to 100 ppm
<code>lmp.transmittance</code>	transmittance of the atmosphere in percent; usually between 60 (humid areas) and 80 percent (deserts)
<code>time.range</code>	numeric vector of length 2: time span (hours of the day) for numerical integration
<code>time.step</code>	time step in hours for numerical integration
<code>start.date</code>	list of length two, giving the start date in day and month components as numbers; these numbers are one-based (SAGA_CMD uses zero-based numbers internally), i.e. Jan. 1st is <code>list(day=1,month=1)</code>

<code>end.date</code>	see <code>start.date</code>
<code>day.step</code>	if <code>days</code> indicates a range of days, this specifies the time step (number of days) for calculating the incoming solar radiation
<code>env</code>	RSAGA geoprocessing environment obtained with rsaga.env ; this argument is required for version control (see Note)
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor

Details

According to SAGA GIS 2.0.7 documentation, "Most options should do well, but TAPES-G based diffuse irradiance calculation ("Atmospheric Effects" methods 2 and 3) needs further revision!" I.e. be careful with `method = "components"` and `method = "lumped"`.

Note

This module is computationally very intensive (depending on the size of the grid and the time resolution, of course). I am currently experimenting with a wrapper for `rsaga.pisr` that distributes the workload over several processors by launching child processes.

SAGA_CMD uses zero-based days and months, but this R function uses the standard one-based days and months (e.g. day 1 is the first day of the month, month 1 is January) and translates to the SAGA system.

This function uses module Potential Incoming Solar Radiation from SAGA library `ta_lighting` in SAGA version 2.0.6+.

rsaga.sgrd.to.esri	<i>Convert SAGA grids to ESRI ASCII/binary grids</i>
--------------------	------------------------------------------------------

Description

rsaga.sgrd.to.esri converts grid files from SAGA's (version 2) grid format (.sgrd) to ESRI's ASCII (.asc) and binary (.flt) format.

Usage

```
rsaga.sgrd.to.esri(in.sgrds, out.grids, out.path, format = "ascii",
  georef = "corner", prec = 5, ...)
```

Arguments

in.sgrds	character vector of SAGA grid files (.sgrd) to be converted; files are expected to be found in folder <code>rsaga.env()\$workspace</code> , or, if an optional env argument is provided, in <code>env\$workspace</code>
out.grids	character vector of ESRI ASCII/float output file names; defaults to in.sgrds with the file extension being replaced by .asc or .flt, depending on format. Files will be placed in folder out.path, existing files will be overwritten
out.path	folder for out.grids
format	output file format, either "ascii" (default; equivalent: format=1) for ASCII grids or "binary" (equivalent: 0) for binary ESRI grids (.flt).
georef	character: "corner" (equivalent numeric code: 0) or "center" (default; equivalent: 1). Determines whether the georeference will be related to the center or corner of its extreme lower left grid cell.
prec	number of digits when writing floating point values to ASCII grid files; either a single number (to be replicated if necessary), or a numeric vector of length length(in.grids)
...	optional arguments to be passed to <code>rsaga.geoprocessor</code> , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the intern argument passed to the `rsaga.geoprocessor`. For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 0 from the SAGA library io_grid.

rsaga.sink.removal *Sink Removal*

Description

Remove sinks from a digital elevation model by deepening drainage routes or filling sinks.

Usage

```
rsaga.sink.removal(in.dem, in.sinkroute, out.dem, method = "fill", ...)
```

Arguments

in.dem	input: digital elevation model (DEM) as SAGA grid file (default file extension: .sgrd)
in.sinkroute	optional input: sink route grid file
out.dem	output: modified DEM
method	character string or numeric value specifying the algorithm (partial string matching will be applied): "deepen drainage route" (or 0): reduce the elevation of pixels in order to achieve drainage out of the former sinks "fill sinks" (or 1): fill sinks until none are left
...	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 1 from SAGA library ta_preprocessor.

```

rsaga.sink.route	<i>Sink Drainage Route Detection</i>
------------------	--------------------------------------

Description

Sink drainage route detection.

Usage

```
rsaga.sink.route(in.dem, out.sinkroute, threshold, thrsheight = 100, ...)
```

Arguments

in.dem	input: digital elevation model (DEM) as SAGA grid file (default file extension: .sgrd)
out.sinkroute	output: sink route grid file: non-sinks obtain a value of 0, sinks are assigned an integer between 0 and 8 indicating the direction to which flow from this sink should be routed
threshold	logical: use a threshold value?
thrsheight	numeric: threshold value (default: 100)
...	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Value

The type of object returned depends on the intern argument passed to the [rsaga.geoprocessor](#). For intern=FALSE it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

I assume that flow directions are coded as 0 = north, 1 = northeast, 2 = east, ..., 7 = northwest, as in [rsaga.fill.sinks](#).

This function uses module 0 from SAGA library ta_preprocessor.

Author(s)

Alexander Brenning (R interface), Olaf Conrad (SAGA module)

```

rsaga.solar.radiation *Potential incoming solar radiation*

Description

This function calculates the potential incoming solar radiation in an area either using a lumped atmospheric transmittance model or estimating it based on water and dust content. Use [rsaga.pisr](#) instead with SAGA GIS 2.0.6+.

Usage

```
rsaga.solar.radiation(in.dem, out.grid, out.duration, latitude,
  unit = c("kWh/m2", "J/m2"), solconst = 1367,
  method = c("lumped", "components"), transmittance = 70,
  pressure = 1013, water.content = 1.68, dust = 100,
  time.range = c(0, 24), time.step = 1, days = list(day = 21, month = 3),
  day.step = 5, env = rsaga.env(), ...)
```

Arguments

in.dem	name of input digital elevation model (DEM) grid in SAGA grid format (default extension: .sgrd)
out.grid	output grid file for potential incoming solar radiation sums
out.duration	Optional output grid file for duration of insolation
latitude	Geographical latitude in degree North (negative values indicate southern hemisphere)
unit	unit of the out.grid output: "kWh/m2" (default) or "J/m2"
solconst	solar constant, defaults to 1367 W/m2
method	specifies how the atmospheric components should be accounted for: either based on a lumped atmospheric transmittance as specified by argument transmittance ("lumped", or numeric code 0; default); or by calculating the components corresponding to water and dust ("components", code 1)
transmittance	transmittance of the atmosphere in percent; usually between 60 (humid areas) and 80 percent (deserts)
pressure	atmospheric pressure in mbar
water.content	water content of a vertical slice of the atmosphere in cm: between 1.5 and 1.7cm, average 1.68cm (default)
dust	dust factor in ppm; defaults to 100ppm

<code>time.range</code>	numeric vector of length 2: time span (hours of the day) for numerical integration
<code>time.step</code>	time step in hours for numerical integration
<code>days</code>	either a list with components day and month specifying a single day of the year for radiation modeling; OR a numeric vector of length 2 specifying the start and end date (see Note below)
<code>day.step</code>	if days indicates a range of days, this specifies the time step (number of days) for calculating the incoming solar radiation
<code>env</code>	RSAGA geoprocessing environment obtained with rsaga.env ; this argument is required for version control (see Note)
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor

Note

This module ceased to exist under SAGA GIS 2.0.6+, which has a similar (but more flexible) module Potential Solar Radiation that is interfaced by [rsaga.pisr](#).

SAGA_CMD uses zero-based days and months, but this R function uses the standard one-based days and months (e.g. day 1 is the first day of the month, month 1 is January) and translates to the SAGA system.

In SAGA 2.0.2, solar radiation sums calculated for a range of days, say `days=c(a,b)` actually calculate radiation only for days `a, ..., b-1` (in steps of `day.step` - I used `day.step=1` in this example). The setting `a=b` however gives the same result as `b=a+1`, and indeed `b=a+2` gives twice the radiation sums and potential sunshine duration that `a=b` and `b=a+1` both give.

The solar radiation module of SAGA 2.0.1 had a bug that made it impossible to pass a range of days of the year or a range of hours of the day (`time.range`) to SAGA. These options work in SAGA 2.0.1.

This function uses module Incoming Solar Radiation (code: 2) from SAGA library `ta_lighting`.

Examples

```
## Not run:
# potential solar radiation on Nov 7 in Southern Ontario...
rsaga.solar.radiation("dem", "solrad", "soldur", latitude=43,
  days=list(day=7, month=11), time.step=0.5)
```

```
## End(Not run)
```

```
rsaga.target
```

```
Define target grid for interpolation
```

Description

Define the resolution and extent of a target grid for interpolation by SAGA modules based on (1) fitting the extent to the input data, (2) an existing SAGA grid file, (3) user-defined parameters, or (4) the header data of an ASCII grid. Intended to be used with RSAGA's interpolation functions. WARNING: THIS FUNCTION LIKELY DOESN'T WORK WITH SAGA GIS 2.0.5 BECAUSE OF A CHANGE IN THE PARAMETERIZATION OF TARGET GRIDS...

Usage

```
rsaga.target(target = c("user.defined", "grid.system",
  "target.grid", "header"),
  user.cellsize = 100, user.fit.extent = TRUE,
  user.x.extent, user.y.extent, user.bbox,
  system.nx, system.ny, system.xy, system.d,
  target.grid, header)
```

Arguments

target	character: method used for defining the target grid
user.fit.extent	Only for target="user.defined": logical; if TRUE, use the dimensions of an input grid supplied to the SAGA module, e.g. to <code>rsaga.ordinary.kriging</code> . The other user.* variables should not be provided if user.fit.extent=TRUE.
user.cellsize	Only for target="user.defined": raster resolution
user.x.extent, user.y.extent	Only for target="user.defined": numeric vectors of length 2: minimum and maximum coordinates of grid cell center points
user.bbox	Only for target="user.defined": alternative way of specifying extent (either use bbox OR user.*.extent): 2x2 matrix of the form <code>rbind(user.x.extent, user.y.extent)</code> .
system.nx, system.ny	Only for target="grid.system": number of columns and rows of the grid
system.xy	Only for target="grid.system": numeric vector of length 2 giving the x and y coordinates at the center of the grid's lower left cell
system.d	Only for target="grid.system": cellsize
target.grid	Only for target="target.grid": character string giving the name of a SAGA grid file that specifies the extent and resolution of the target grid
header	Only for target="header": list: ASCII grid header (as returned e.g. by read.ascii.grid.header) or defined manually; must at least have components <code>ncols</code> , <code>nrows</code> , <code>cellsize</code> , and either <code>x/yllcorner</code> or <code>x/yllcenter</code> .

Note

This function is to be used with RSAGA functions [rsaga.ordinary.kriging](#), [rsaga.inverse.distance](#), [rsaga.nearest.neighbour](#) and [rsaga.modified.quadratic.shephard](#) Note that these are currently only compatible with SAGA GIS 2.0.4.

## End(Not run)
```

rsaga.wetness.index *SAGA Modules SAGA Wetness Index*

Description

Calculate the SAGA Wetness Index (SWI), a modified topographic wetness index (TWI)

Usage

```
rsaga.wetness.index( in.dem, out.wetness.index,
  out.carea, out.cslope, out.mod.carea, t.param, ...)
```

Arguments

in.dem	input: digital elevation model (DEM) as SAGA grid file (default file extension: .sgrd)
out.wetness.index	output (optional): wetness index grid. Existing files of the same name will be overwritten!

<code>out.carea</code>	output (optional): catchment area
<code>out.cslope</code>	output (optional): catchment slope
<code>out.mod.carea</code>	output (optional): modified catchment area
<code>t.param</code>	positive numeric value (optional): undocumented
<code>...</code>	optional arguments to be passed to rsaga.geoprocessor , including the env RSAGA geoprocessing environment

Details

The SAGA Wetness Index is similar to the Topographic Wetness Index (TWI), but it is based on a modified catchment area calculation (`out.mod.carea`), which does not treat the flow as a thin film as done in the calculation of catchment areas in conventional algorithms. As a result, the SWI tends to assign a more realistic, higher potential soil wetness than the TWI to grid cells situated in valley floors with a small vertical distance to a channel.

Value

The type of object returned depends on the `intern` argument passed to the [rsaga.geoprocessor](#). For `intern=FALSE` it is a numerical error code (0: success), or otherwise (default) a character vector with the module's console output.

Note

This function uses module 15 from the SAGA library `ta_hydrology`.

set.file.extension	<i>Determine or modify file name extensions</i>
--------------------	-------------------------------------------------

Description

Function `get.file.extension` determines the file extension, `set.file.extension` changes it, and `default.file.extension` changes it only if it is not already specified.

Usage

```
set.file.extension(filename, extension, fsep = .Platform$file.sep)
get.file.extension(filename, fsep = .Platform$file.sep)
default.file.extension(filename, extension, force = FALSE)
```

Arguments

filename	character vector: file name(s), possibly including paths and extensions; a file name ending with a "." is interpreted as having extension "", while a file name that doesn't contain a "." is interpreted as having no extension
extension	character string: file extension, without the dot
fsep	character: separator between paths
force	logical argument to <code>default.file.extension</code> : force the file extension to be extension (same result as <code>set.file.extension</code>), or only set it to extension if it has not been specified?

Value

character vector of same length as filename

Author(s)

Alexander Brenning

Examples

```
fnm = c("C:/TEMP.DIR/temp", "C:/TEMP.DIR/tmp.txt", "tempfile.")
get.file.extension(fnm)
set.file.extension(fnm, extension=".TMP")
default.file.extension(fnm, extension=".TMP")
```

wind.shelter

*Wind Shelter Index***Description**

wind.shelter is a function to be used with [focal.function](#) to calculate a topographic wind shelter index from a digital elevation model, which is a proxy for snow accumulation on the lee side of topographic obstacles. wind.shelter.prep performs some preparatory calculations to speed up repeated calls to wind.shelter.

Usage

```
wind.shelter(x, prob = NULL, control)
wind.shelter.prep(radius, direction, tolerance, cellsize = 90)
```

Arguments

x	square matrix of elevation data
prob	numeric: quantile of slope values to be used in computing the wind shelter index; if NULL, use max (equivalent to prob=1)
control	required argument: the result of a call to wind.shelter.prep
radius	radius (>1) of circle segment to be used (number of grid cells, not necessarily an integer)
direction	wind direction: direction from which the wind originates; North = 0 = 2*pi, clockwise angles.
tolerance	directional tolerance
cellsize	grid cellsize

Details

wind.shelter implements a wind shelter index used by Plattner et al. (2004) for modeling snow accumulation patterns on a glacier in the Austrian Alps. It is a modified version of the algorithm of Winstral et al. (2002). The wind shelter index of Plattner et al. (2004) is defined as:

$$\text{Shelter index}(S) = \arctan(\max((z(x_0) - z(x)) / |x_0 - x| : x \in S)),$$

where $S = S(x_0, a, da, d)$ is the set of grid nodes within a distance $\leq d$ from x_0 , only considering grid nodes in directions between $a - da$ and $a + da$ from x_0 .

The present implementation generalizes this index by replacing max by the quantile function; the max function is used if prob=NULL, and the same result is obtained for prob=1 using the quantile function.

Value

The function `wind.shelter` returns the wind shelter index as described above if a numeric matrix `x` is provided. If it is missing, it returns the character string "windshelter".

`wind.shelter.prep` returns a list with components `mask` and `dist`. Both are square matrices with $2 * (\text{ceiling}(\text{radius}) + 1)$ columns and rows:

<code>mask</code>	indicates which grid cell in the moving window is within the specified circle segment (value FALSE) or not (TRUE)
<code>dist</code>	the precomputed distances of a grid cell to the center of the moving window, in map units

Note

The wind shelter index only makes sense if elevation is measured in the same units as the horizontal map units used for the `cellsize` argument (i.e. usually meters).

`wind.shelter` and `wind.shelter.prep` do not restrict the calculation onto a circular area; this is done by [focal.function](#) when used in combination with that function (assuming `search.mode="circle"`).

Note that the present definition of the wind shelter index returns negative values for surfaces that are completely exposed toward the specified direction. This may make sense if interpreted as a "wind exposure index", or it might be appropriate to set negative wind shelter values to 0.
